Re: Coarsegold Area Report

Dear Greg:

Submitted herewith is our report on groundwater conditions in the Coarsegold area. We appreciate the cooperation of the Picayune Rancheria of the Chukchansi Indian community, Yosemite Springs Park Utility, Madera County RMA staff, California Department of Health Services, and private well owners in the area in conducting this evaluation.

Sincerely Yours,

Kenneth D. Schmidt

GROUNDWATER CONDITIONS IN THE COARSEGOLD AREA

INTRODUCTION

In 2005, Kenneth D. Schmidt and Associates (KDSA) completed a hydrogeologic evaluation of the area in the vicinity of the Picayune Rancheria/Indian Lakes, as part of the agreement between Madera County and the Picayune Rancheria of the Chukchansi Indians. Madera County received an IRWMP (Prop 50) grant from the Department of Water Resources (DWR) in 2006. One component of the grant was a hydrogeologic evaluation of the hardrock in the Coarsegold area. Other hydrogeologic studies were conducted at this time in the North Fork and the Raymond-Hensley Lake areas, as part of a DWR AB 303 grant. This report discusses the results of the Coarsegold area hydrogeologic evaluation. Prior to this report, a hydrogeologic evaluation for the entire Coarsegold area was not available.

Figure 1 shows the location of the Coarsegold study area. A study area was selected to cover most of the developed areas at and near Coarsegold. The study area boundary on the north is generally near the watershed boundary between the Fresno River watershed and the Coarsegold Creek watershed. The study area boundary on the west is generally a north-south line running through the confluence of the Fresno River and Coarsegold Creek (the southwest corner of the study area). The study area boundary on the south is near an east-west line south of the Yosemite Lakes subdivision and near the

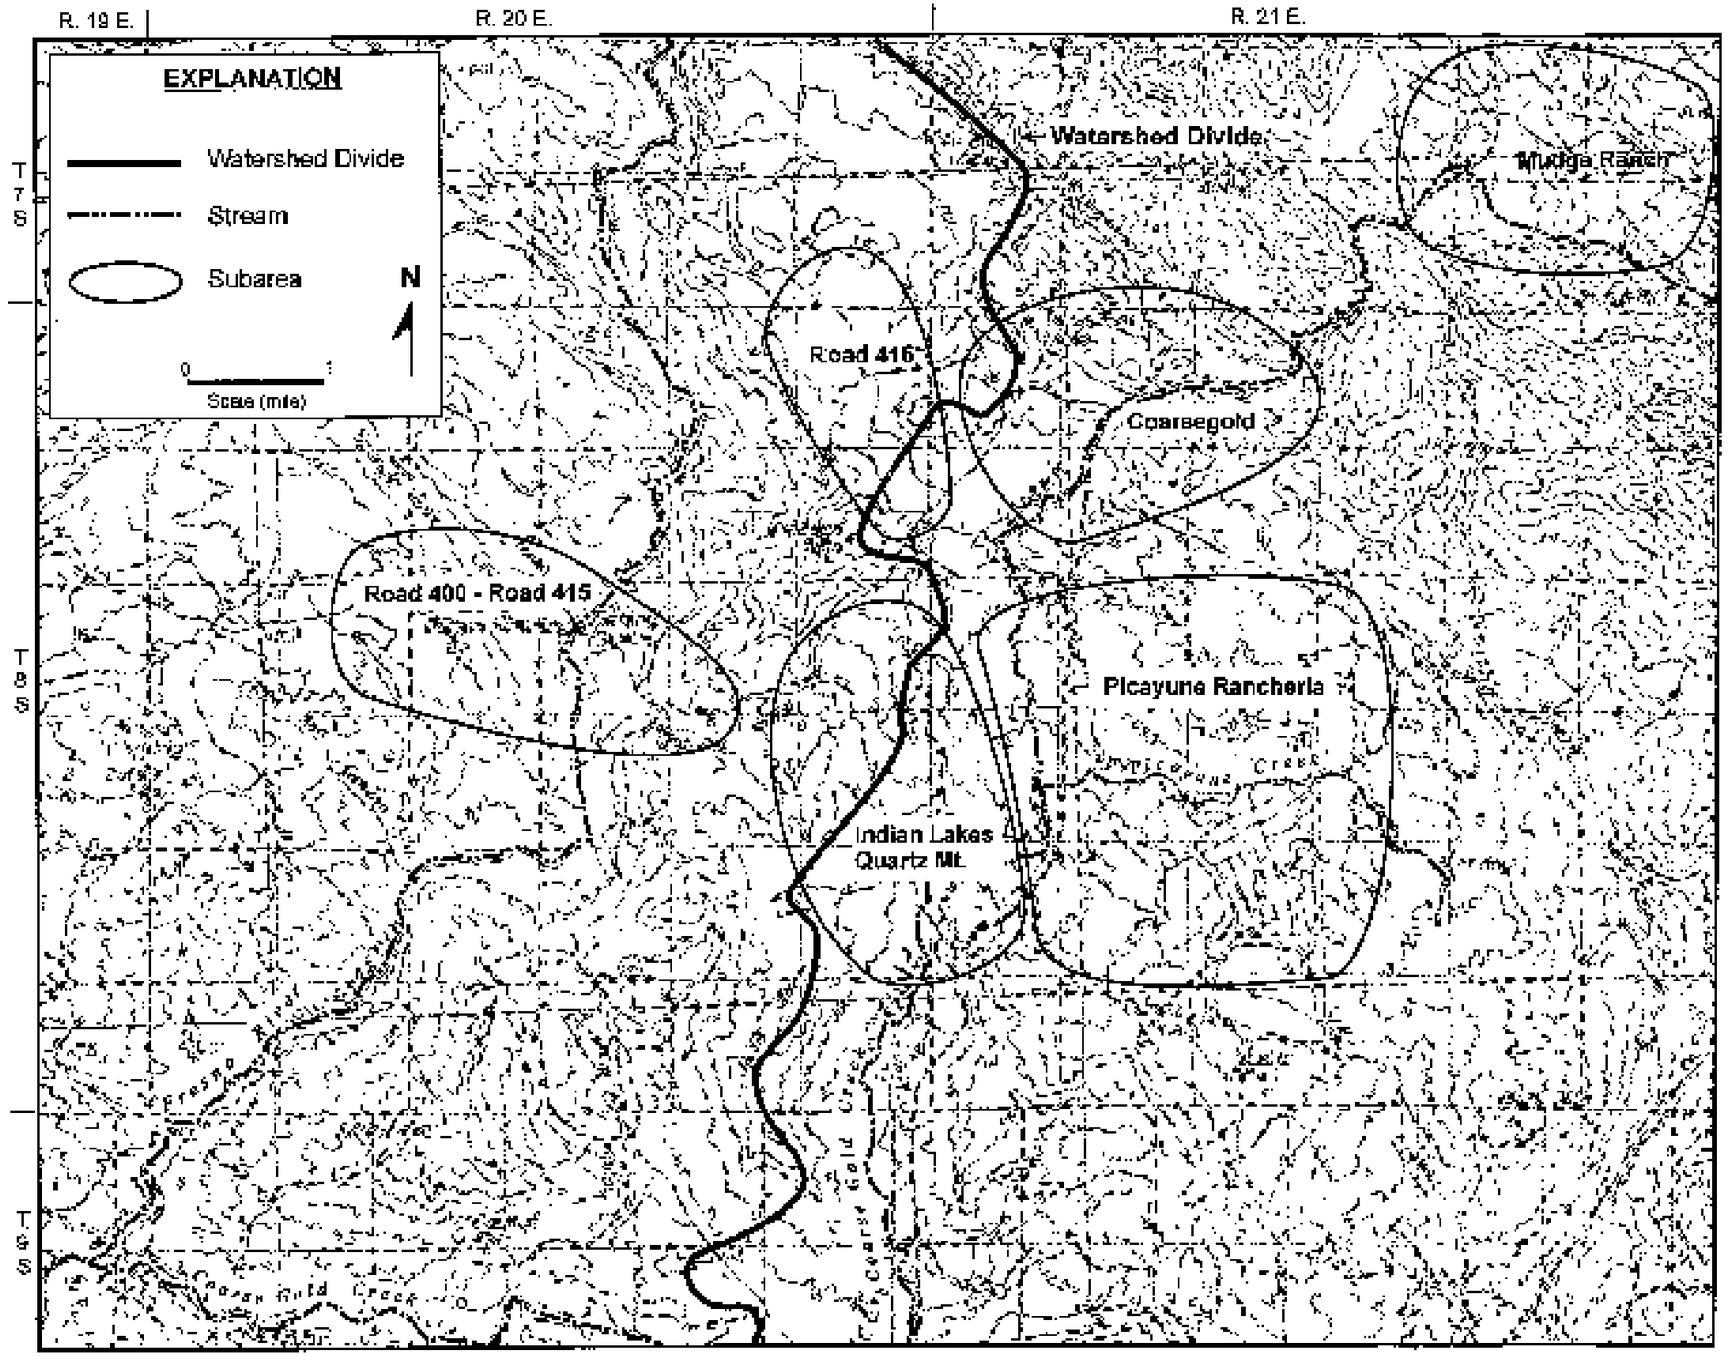

FIGURE 1 - STREAMS, WATERSHEDS, AND SUBAREAS IN THE COARSEGOLD AREA

Coarsegold Creek. The easterly boundary is a north-south line just east of Mudge Ranch and near the east edge of the Picayune Creek watershed. Highway 41 extends through Coarsegold. The Coarsegold area is bounded by Potter Ridge and Thornberry Mountain on the north and Buford Mountain on the west.

The Fresno River is the largest drainage in the Coarsegold area, and extends south through the west part of the study area. Much of the Coarsegold area is drained by Coarsegold Creek, a tributary of the Fresno River. The confluence of Coarsegold Creek and the Fresno River is southwest of the Yosemite Lakes subdivision. Land surface elevations in the Coarsegold area range from about 860 feet above mean sea level near the confluence of Coarsegold Creek and the Fresno River to more than 3,400 feet along part of Potter Ridge and part of Thornberry Mountain, north of Coarsegold.

PRECIPITATION

Precipitation is the ultimate source of both surface water and groundwater in the Coarsegold area. Precipitation records are available for Coarsegold back to 1976 (Table 1). The lowest annual precipitation has been between 13 and 17 inches. In contrast, the annual precipitation has exceeded 30 inches in wet years. The average annual precipitation at this station was about 27 inches from 1978 to 2006. Of this amount, most falls during November-

source: National Climatic Data Center

April. The lowest monthly precipitation (less than one inch) is normally during June and September. An isophyetal map of mean annual precipitation (Figure 2) from the California Department of Water Resources (1956) indicates values ranging from less than 16 inches near the confluence of Coarsegold Creek and Fresno River, to about 30 inches near Mudge Ranch. This range is associated with the large range in land surface elevations. Both elevations and precipitation generally increase to the northeast in the Coarsegold area. Appendix A contains precipitation records for the Coarsegold area.

EVAPOTRANSPIRATION ESTIMATES

In most foothill and mountain areas, groundwater pumping comes from water that would otherwise have run off as streamflow or have been consumed by evapotranspiration. Estimates of evapotranspiration of vegetation in the foothills and mountains of the Central Sierra Nevada were provided by KDSA (2005). For most high elevation parts of the watersheds in the Coarsegold area, where conifer forests present, the evapotranspiration is about 24 inches of water per year. In contrast, for the lower elevation lands in the southwest part of the Coarsegold area, evapotranspiration from the grass-oak woodland is expected to be about 16 inches per year. The relation between precipitation and evapotranspiration means that most of the streamflow originates in the higher part of the

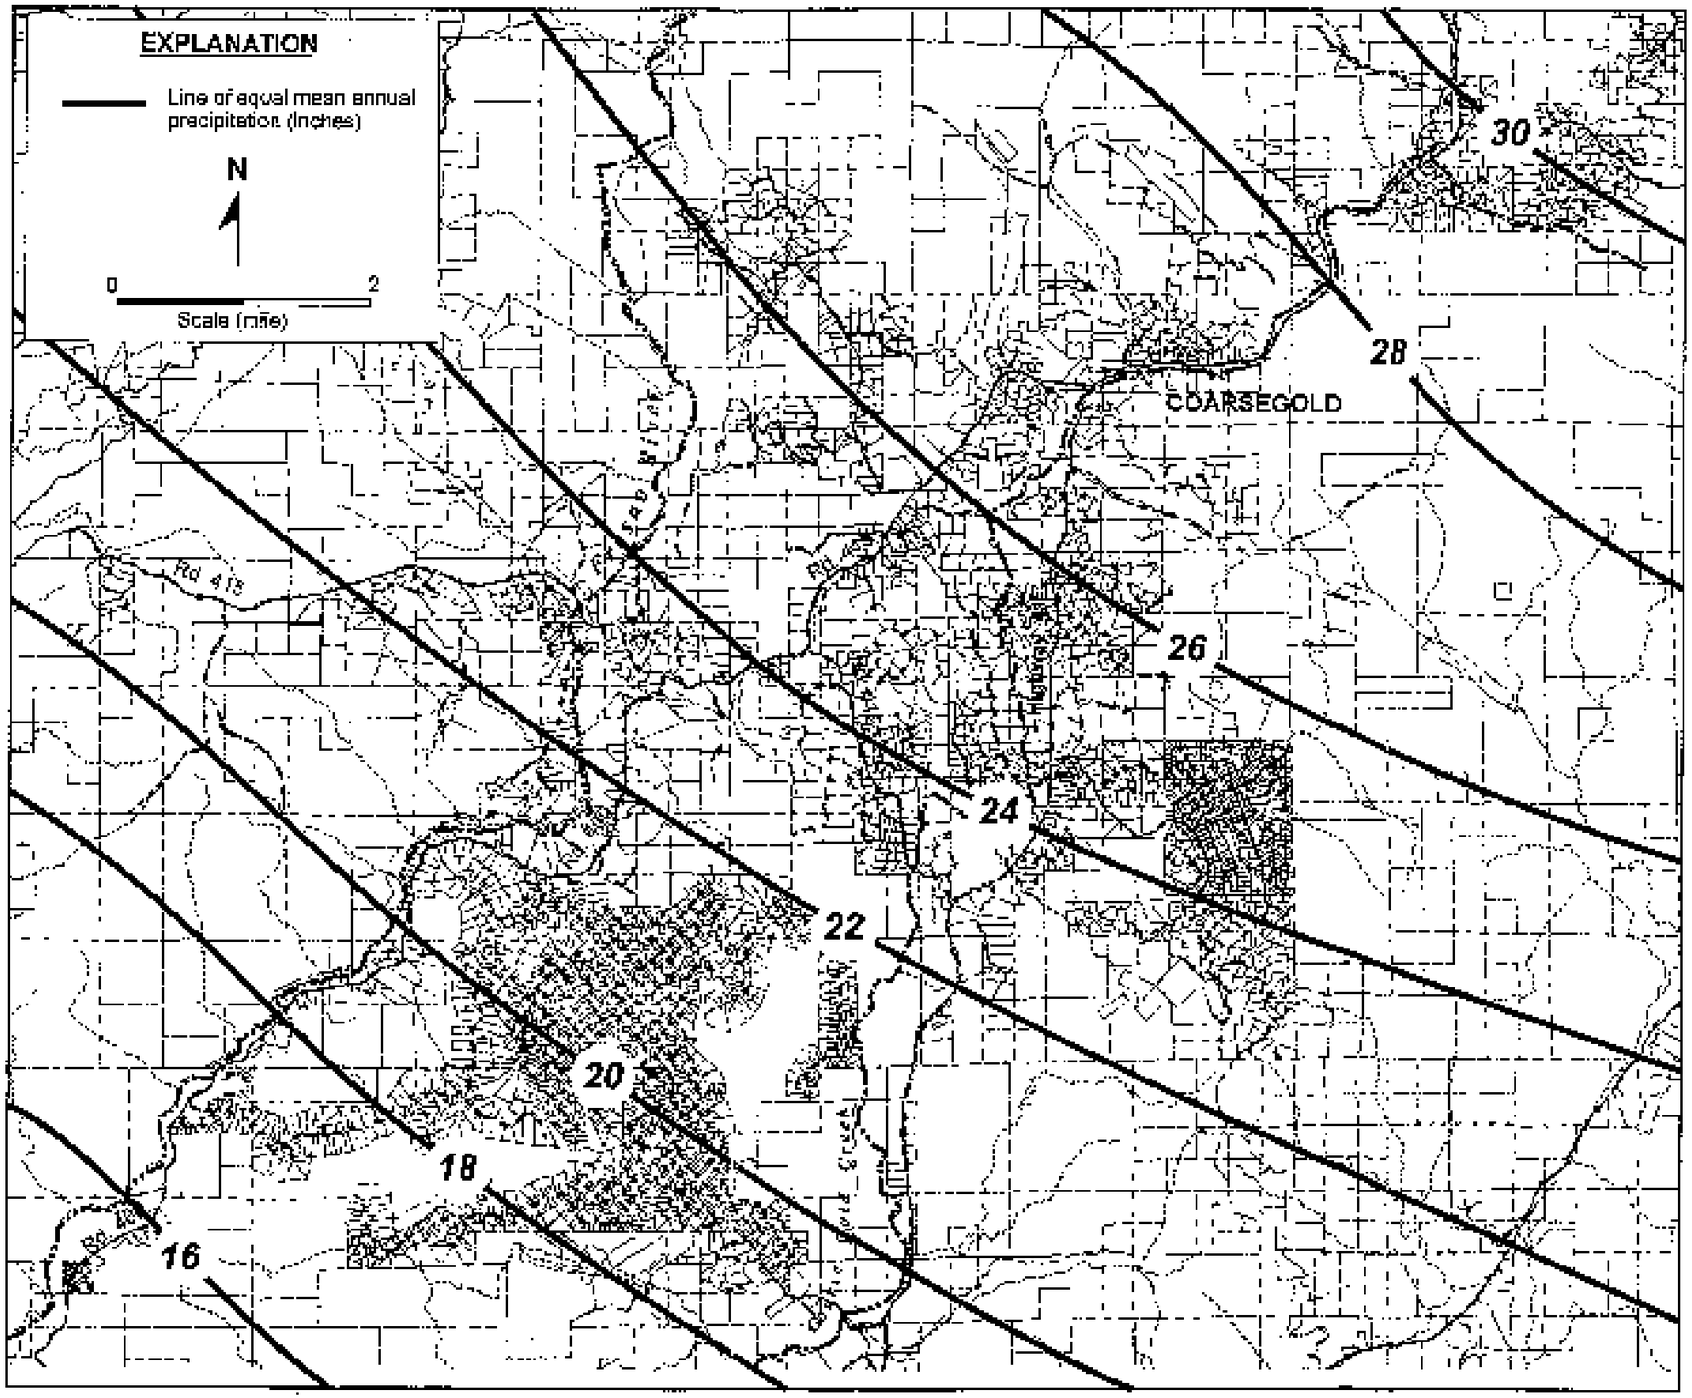

FIGURE 2 - MEAN ANNUAL PRECIPITATION (INCHES)

Coarsegold Creek watershed.

WATERSHEDS AND STREAMFLOW

Figure 1 shows local watersheds in the Coarsegold area. The largest watershed is that of Coarsegold Creek and the next largest is Picayune Creek. Records of streamflow in the Coarsegold area were obtained from the U.S. Geological Survey National Water Information website, and are provided in Appendix B. Station 1125700 was located on Picayune Creek, just upstream of the confluence with Coarsegold Creek, and the drainage area above the gage was 8.17 square miles. Streamflow records are available for this station from 1964 to 1968. The annual streamflow ranged from about 700 acre-feet to 5,000 acre-feet during this period, and the average was 2,900 acre-feet. This period was wetter than normal.

Boyle Engineering Corporation (1973) delineated a 39,500-acre watershed for Coarsegold Creek above Blackhawk reservoir and estimated a mean annual runoff of about 9,000 acre-feet per year. Blackhawk Reservoir when full can store 650 acre-feet of water and covers a 51-acre area. At one time, Yosemite Lakes had an agreement with MID to use up to 2,000 acre-feet per year of water from Coarsegold Creek or the Fresno River, as a backup for the well supply.

In the northeast part of the Coarsegold area, where the mean annual precipitation exceeds about 24 inches, there is an average

excess of precipitation over evapotranspiration of about six inches per year, which would runoff as streamflow. There is a 59-square mile watershed on Coarsegold Creek above the confluence with the Fresno River. Using an average annual precipitation on the watershed of 24 inches, an average annual evapotranspiration of about 18 inches, and a consumptive use of about 1,200 acre-feet per year, the average annual streamflow in Coarsegold Creek near the confluence would be about 18,000 acre-feet per year. The average of 9,000 and 18,000 acre-feet per year, or 13,500 acre feet per year is probably the best value for this streamflow.

GEOLOGIC CONDITIONS

Bateman (1992) prepared a map of rock types in the Bass Lake-Oakhurst area, which includes the Coarsegold area. Figure 3 is a modified version of this map for the Coarsegold area. Most of the rock outcrops in the area are granitic rocks, and the Bass Lake tonalite is the most widespread of these. There is a fairly large area of metamorphic rocks (phyllite and greenstone) in the northeast part of the Coarsegold area, extending through the town of Coarsegold. Also shown are the strikes and dips of foliations in the rock outcrops, which generally are similar to fracture patterns, and fractures that were mapped in rock outcrops as part of this evaluation. The predominant fracture pattern trend in most of the Coarsegold Area is northwest-southeast, and the fractures are steeply dipping or near vertical, except in the southeast part of

the area, where the dip is commonly less than 45 degrees. Also, fracture patterns in this part of the study area have variable orientations.

SUPPLY WELLS

Both large and small water systems are present in the Coarsegold area. Water system wells provide most of the water for development in the south part of the Coarsegold area. However, private wells outside of these systems provide most of the water used in the north part of the area (discussed in a subsequent section of the report).

Large Water Systems

Large water systems in the Coarsegold area include:

Madera County MD SA 1 (Indian Lakes)

Madera County MD 40 (Sunset Mountain)

Madera County MD 63-A (Meadow Springs Ranch)

Madera County MD 73-A (Quartz Mountain)

Coarsegold Highlands

Yosemite Spring Park Utility (Yosemite Lakes).

Figure 4 shows locations of water systems and wells in the area north of the Yosemite Lakes subdivision.

Indian Lakes

Indian Lakes (Madera County SA 1) is located and east of the

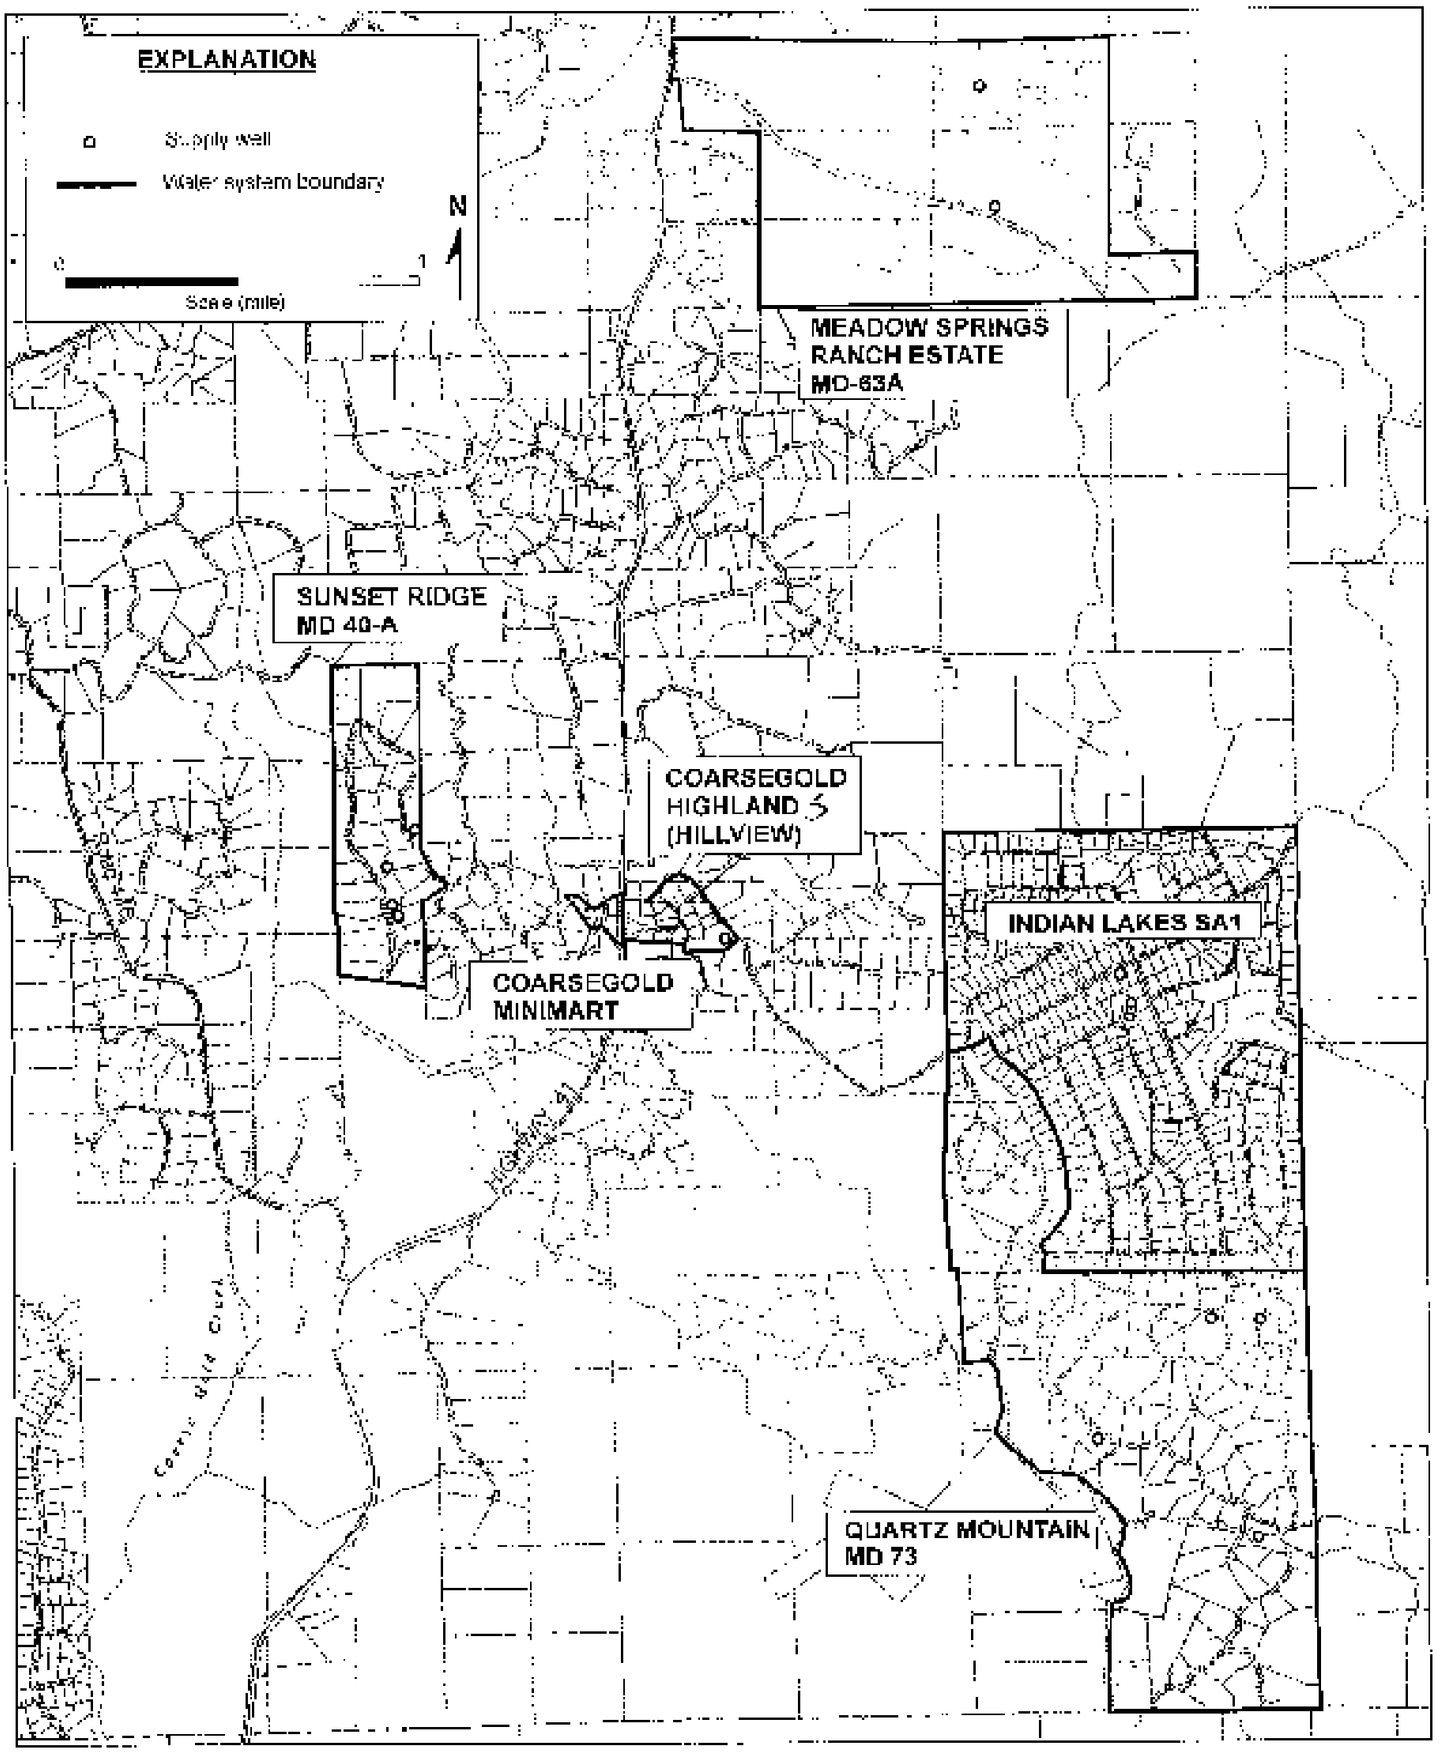

FIGURE 4 - LOCATIONS OF WATER SYSTEMS AND WELLS
NORTH OF YOSEMITE LAKES SUBDIVISION

Picayune Rancheria and had 464 connections in 2006. All of the active water system wells are located just south of Road 417 near the large water storage tanks. Table 2 provides information on the presently active Indian Lakes water system wells. As of late 2006, there were five active wells (No. 4, 5, 6, 7, and 8). Wells No. 4 and 5 range from 365 to 370 feet in depth and Well No. 6 is 750 feet deep. Wells No. 7 and 8 were drilled in early 2005 to depths of 932 and 1,082 feet, respectively, and are two of the deepest wells in the Coarsegold area.

The major water-producing zones in the active water system wells are in the following depth intervals:

Well No.	Depth (feet)
4	300-325
5	295-335
6	330-331 & 557-558
7	415-452 & 882-883
8	612-613, 927-978 & 1,058-1,059

Pumpage from the Indian Lakes wells is measured, and the pumpage was 224 acre-feet in 2006. Except for the Yosemite Springs Park Utility, this is the largest amount of concentrated pumpage in the study area.

There are a number of unused water system wells in the Indian

TABLE 2-CONSTRUCTION DATA FOR INDIAN LAKES WATER SYSTEM WELLS

No.	Date Drilled	Total Depth (ft)	Cased Depth (ft)	Casing Diam (in)	Airlift (gpm)	Pumping Rate (gpm)
4	7/66	365	68	6	15	10
5	6/88	370	73	12	300	298
6	12/99	750	100	8	150	80
7	2/05	932	100	8	300	-
8	1/05	1,082	100	8	165	-

Data from water well completion reports and Madera County. Well No. 8 was not in service as of 2006.

Lakes Subdivision, most of which are only about 200 to 300 feet deep. These wells were abandoned primarily due to lack of sustained water production.

Quartz Mountain

The Quartz Mountain system (MD 73A) had 125 connections in 2006 and four wells, three of which were active. Figure 4 shows the locations of these wells and Table 3 provides construction information. Depths of these wells ranged from 400 to 898 feet. Pumping rates ranged from about 30 to 60 gpm per well. Most of the water production in these wells came from the following depth intervals:

Well No.	Depth (feet)
Willow Pond 1	532-533 & 803-804
Willow Pond 2	591-604, 647-667, & 702-705
Ridge 1	610-620, 705-710, & 820-830
Ridge 2	377-378

Pumpage from the Quartz Mountain wells is measured, and the pumpage was 81 acre-feet in 2006.

Sunset Ridge (MD 40-A)

Sunset Ridge had 27 connections in 2006. Sunset Ridge has three active wells and five additional wells that are unused. Most of the unused wells range in depth from about 250 to 350 feet. Table 4 provides data on the Sunset Ridge active wells as of 2004.

TABLE 3-CONSTRUCTION DATA FOR QUARTZ MOUNTAIN WELLS

TABLE 4-CONSTRUCTION DATA FOR SUNSET RIDGE WELLS

No.	Date Drilled	Total Depth (ft)	Cased Depth (ft)	Casing Diam (in)	Airlift (gpm)	Pumping Rate (gpm)
1	8/90	680	50	6	100	
2	8/90	550	50	6	90	
3	7/90	475	52	6	100	

Data from water well completion reports and Madera County.

Depths of these ranged from 475 to 690 feet. Airlift yields ranged from 30 to 100 gpm. Most of the water production came from the following depth intervals:

Well No.	Depth (feet)
1	679-680
2	Unknown
3	Unknown

Pumpage from these wells was 19 acre-feet in 2006.

Coarsegold Highlands

The Hillview Water Co. Coarsegold Water System serves 22 lots in the area just east of Highway 41 and primarily south of Road 417. The system has two wells. Well No. 1 is 240 feet deep and Well No. 2 is 703 feet deep. The water well drillers report for Well No. 2 indicates that most of the water production was from 320 to 321 feet, 407 to 408 feet, and 702 to 703 feet, respectively. Pumping rates range from less than 15 to 75 gpm. In 2006, the total pumpage from these wells was 9 acre-feet.

Picayune Rancheria

Three wells are used for the Casino (No. 1, 2, and 3), and a fourth (No. 4) is used for the tribal administrative offices. There are three other inactive wells at the Rancheria that were formerly used for homes that have been demolished. These wells are

used only for monitoring. Table 5 summarizes data for the active wells. The Casino wells range in depth from about 380 to 470 feet. The air-lifted yields of these wells ranged from 100 to 300 gpm. Most of the water production from these wells came from the following depth intervals:

Well No.	Depth (feet)
1	415-418, 439-442, & 451-453
2	379
3	310-313, 340-344, & 408-438

Well No. 4 is only 200 feet deep, and had an air-test yield of 25 gpm. Prior to early September 2003, Well No. 2 was the source of water for the Casino. This water was used during construction. Well No. 3 was the primary well used for the Casino between September 2003 and Summer 2007. The total pumpage for the Casino was __ acre-feet in 2006. Pumpage for the Casino is limited, because of the reuse of wastewater effluent. In addition, metered records for the Casino wells indicate that the total pumpage is relatively constant throughout the year. This is an important factor in evaluating water-level trends for wells in the area.

Because of expansion of the Casino in 2007, Well No. 3 had to be destroyed. In August 2005, Walt Bannon Drilling, Inc. of Oakhurst drilled Casino Well No. 5 at a site along Lucky Lane, about 1,500 feet west-southwest of Well No. 3. Well No. 5 was drilled to

TABLE 5-CONSTRUCTION DATA FOR PICAYUNE RANCHERIA WELLS

No.	Date Drilled	Drilled Depth (ft)	Cased Depth (ft)	Perforations (ft)	Airlift (gpm)	Pumping Rate (gpm)

4	11/76	200	40	None	25	-

Data from well completion reports and Chukchansi Indians.

a depth of 1,083 feet, and the uppermost 300 feet of the well was sealed off, to preclude pumping of shallow groundwater. About 125 gpm of water was airlifted from a fracture zone between 392 and 395 feet in depth. An additional 60 to 75 gpm was obtained from a fracture zone between 1,082 and 1,083 feet in depth. The well has yet to be pump tested, and is not yet in service.

Yosemite Springs Park Utility Co.

The Yosemite Springs Park Utility Co. had 21 active water supply wells as of 2006. Locations of the water system and wells are provided in Figure 5. Table 6 provides construction data for these wells. A number of wells were drilled in 1969, primarily in Long Hollow. Most of these earlier wells were only several hundred feet deep. Most of these wells were subsequently abandoned and replaced by deeper wells, and some were deepened. Beginning with Well 34-A in 1981, six deeper wells were drilled, ranging in depth from about 600 to 1,400 feet. Subsequent new wells were usually from about 860 to 1,230 feet deep, depending on where water-producing fractures were found. By 2007, only two wells about 200 feet deep (28-A and 29-A) were still in service. Only two wells about 500 feet deep (31-A and 40-A) were still in service as of 2007. Thus most of the water system production came from wells more than 600 feet deep. Table 6 also shows depths of major water-producing fracture. Most of the active wells are highly productive. Most of the wells

are located in or near Long Hollow, which is indicated to be a major fracture zone-the largest known in the Coarsegold area. Most of the water production for the system in 2006 came from Wells No. 42-A, 40-A, 1-A, 36-A, 37-A, 45-A, and 47-A. All of these wells were drilled or deepened after 1980.

Small Water Systems

Todd Engineers (2003) summarized data on a number of small water systems in the Coarsegold area. Information on these was updated for this evaluation.

System	Connections
The Village	21
Oak Creek MHP	198
Bluff Drive W.C.	6

Individual Wells

Completion reports for individual wells in the Coarsegold area were obtained from the California Department of Water Resources. The completion reports for these wells are considered confidential. Where possible, these logs were matched with parcel numbers available from Madera County. These wells were then associated with specific subareas for farther evaluation. Appendix C contains a summary of well construction data and airtest yields for these individual wells, by subarea (Figure 1).

Mudge Ranch Subarea

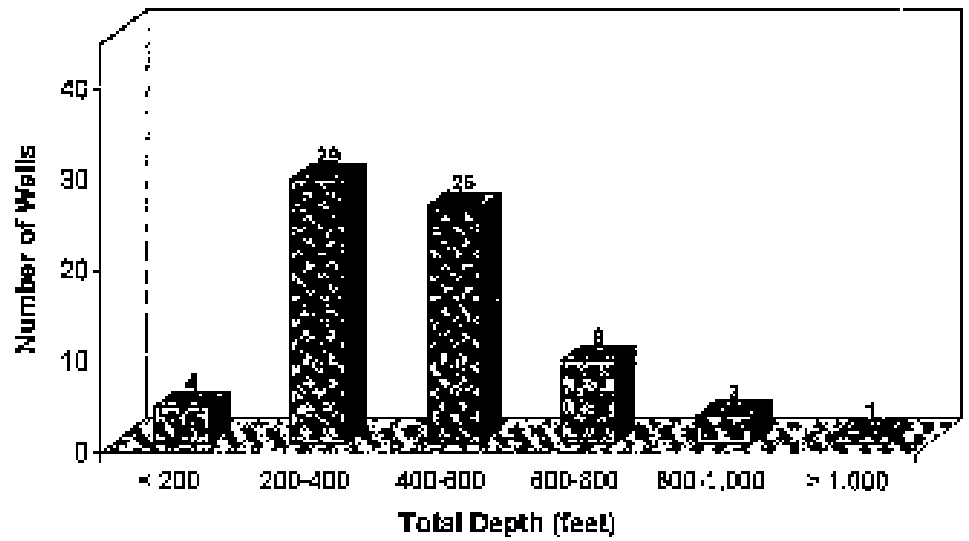
A total of 72 individual wells in the Mudge Ranch subarea had completion reports that could be matched with parcel numbers. Figure 6 shows the range in depth and airtest yields at the time of drilling for these wells. Although airtest yields at the time of drilling aren't necessarily indicative of long-term yields, they provide some indication of the yields. Most of the individual wells with records in this subarea range from 200 to 600 feet in depth. Airtest yields of about 85 percent of these wells exceeded 5 gpm. About two-thirds of these wells had airtest yields exceeding 10 gpm, which is considered good.

Coarsegold Subarea

A total of 84 individual wells had completion reports that could be matched with parcel numbers in the subarea. Figure 7 shows depths and airtest yields for individual wells in this subarea. About half of the individual wells ranged from 200 to 480 feet in depth. Almost 80 percent of the individual wells had airtest yields of more than 5 gpm. About two-thirds of the wells had airtest yields exceeding 10 gpm, which is considered good.

Road 415-Trabuco Road Subarea

Completion reports were available for 98 individual wells that could be matched to parcel numbers in this subarea. Figure 8 shows



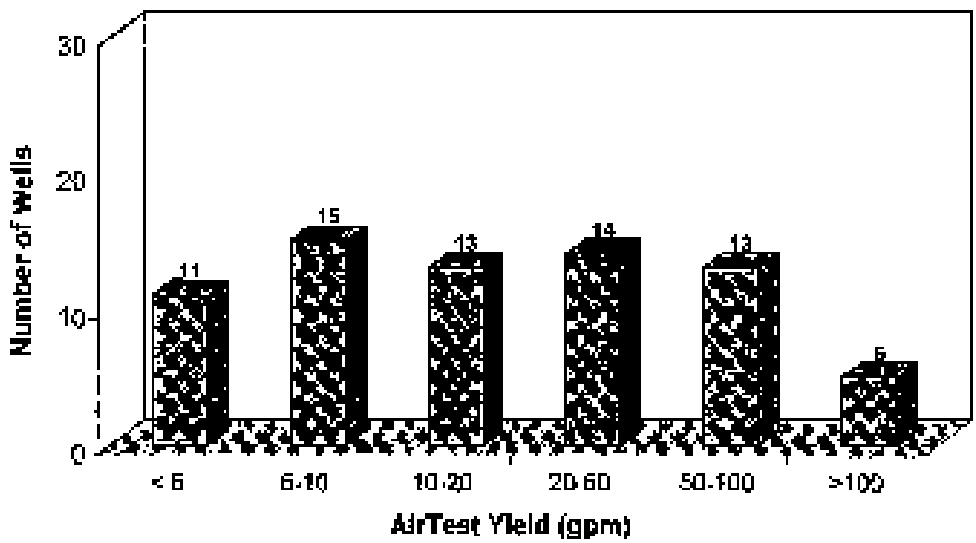


FIGURE 6 - DEPTHS AND AIRTEST YIELDS OF WELLS IN MUDGE RANCH SUBAREA

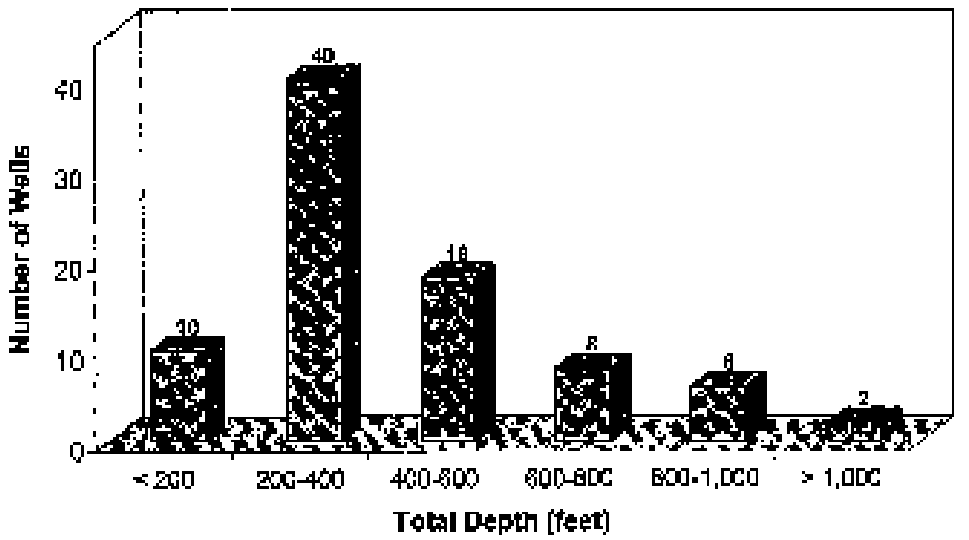

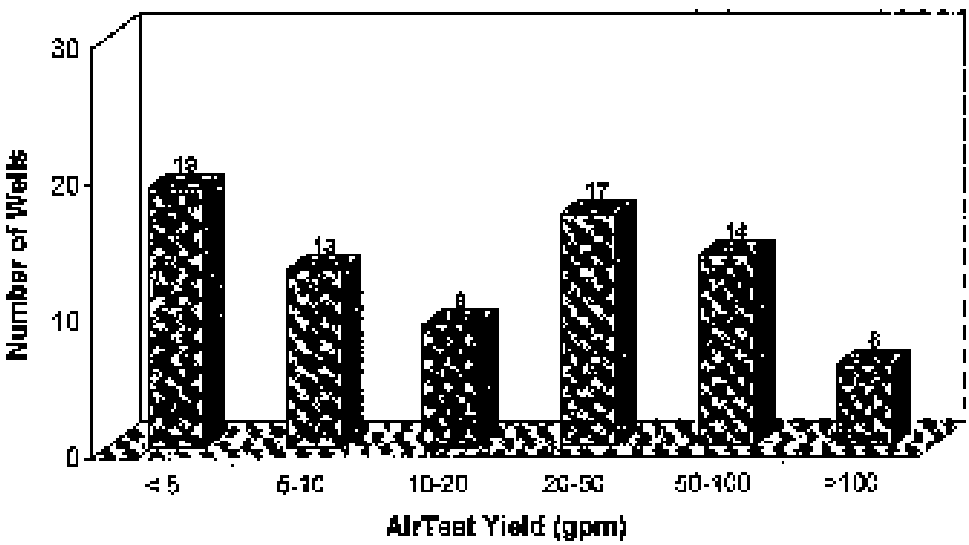

FIGURE 7 - DEPTHS AND AIRTEST YIELDS OF WELLS IN COARSEGOLD SUBAREA

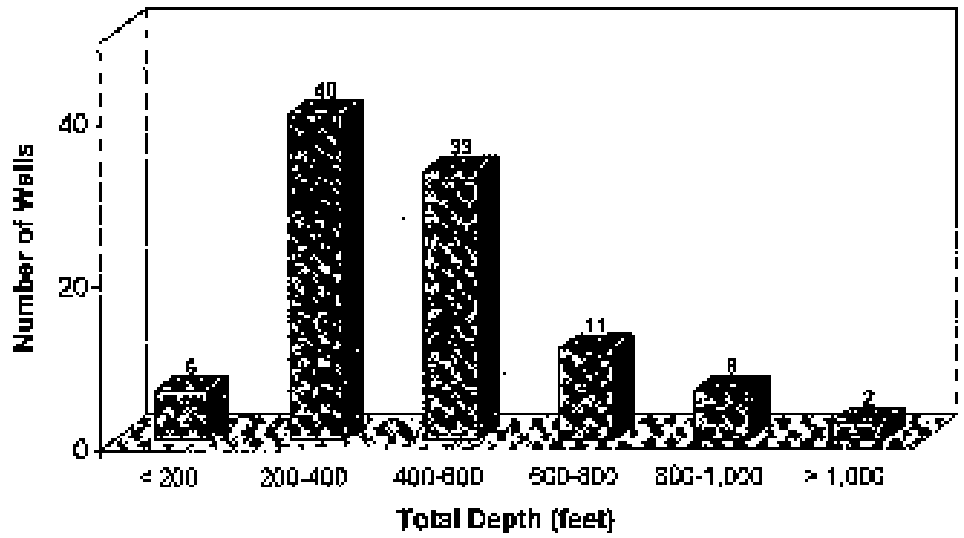

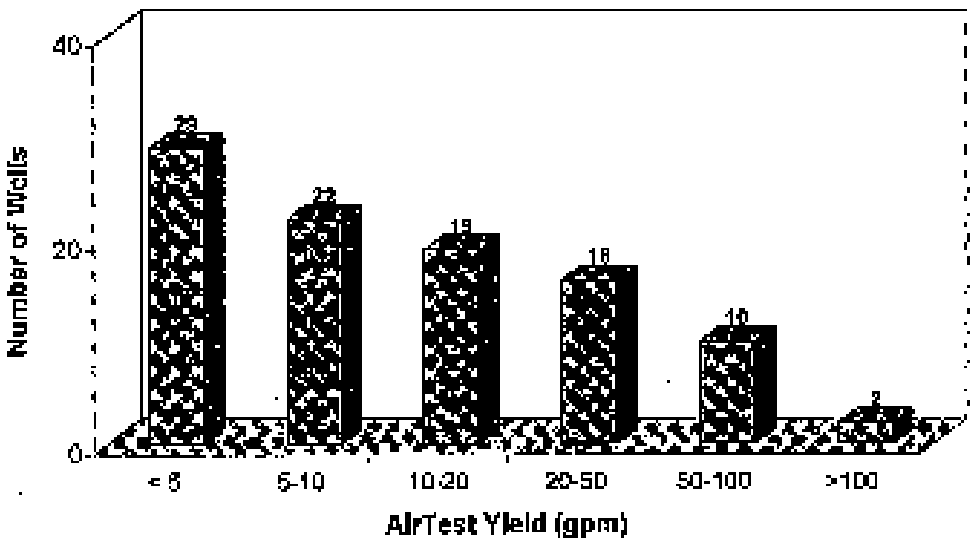

FIGURE 8 - DEPTHS AND AIRTEST YIELDS OF WELLS IN ROAD 415 - TRABUCO ROAD SUBAREA

depths and airtest yields at the time of drilling for wells with completion reports. Almost 80 percent of these wells were less than 600 feet deep. Airtest yields for about 60 percent of the individual wells exceeded 5 gpm. This is indicated to be a less favorable area for well production compared to the two previous subareas.

Road 400-Road 415 Subarea

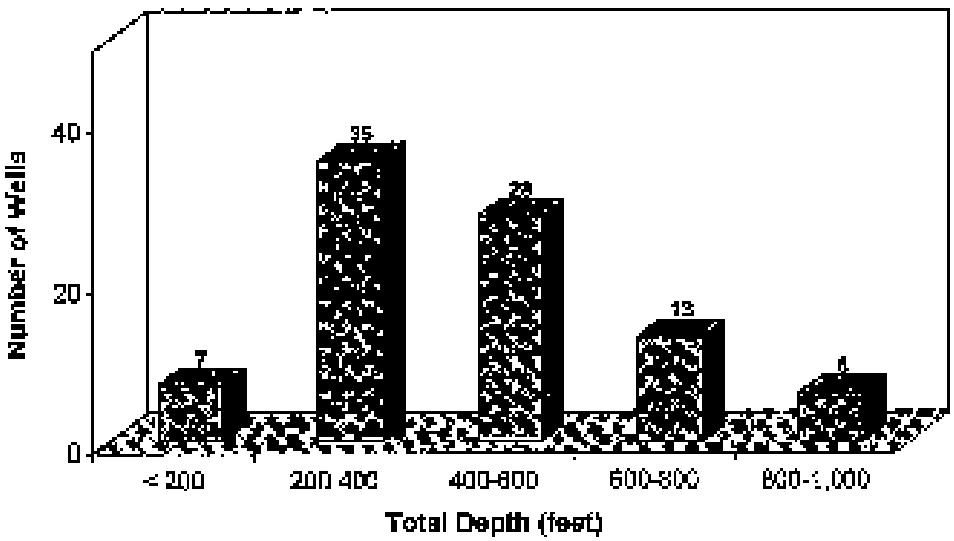
Completion reports were available for 89 individuals wells in this subarea that could be matched to drillers reports. Figure 9 shows the depths and airtest yields at the time of drilling for wells with completion reports. About 70 percent of the wells were less than 600 feet deep. Almost 90 percent of the wells had air-test yields exceeding 5 gpm. About 60 percent had yields exceeding 10 gpm, which is considered good.

Road 416 Subarea

Completion reports were available for 53 wells in the subarea. About half of of these wells ranged from 400 to 600 feet deep, and more than 80 percent were less than 600 feet deep (Figure 10). Airtest yields at the time of drilling for 85 percent of the wells exceeded 5 gpm. Yields for almost three-fourths of these wells exceeded 10 gpm, and this is considered good.

Picayune Rancheria Subarea

Completion reports were available for 82 wells in this sub-



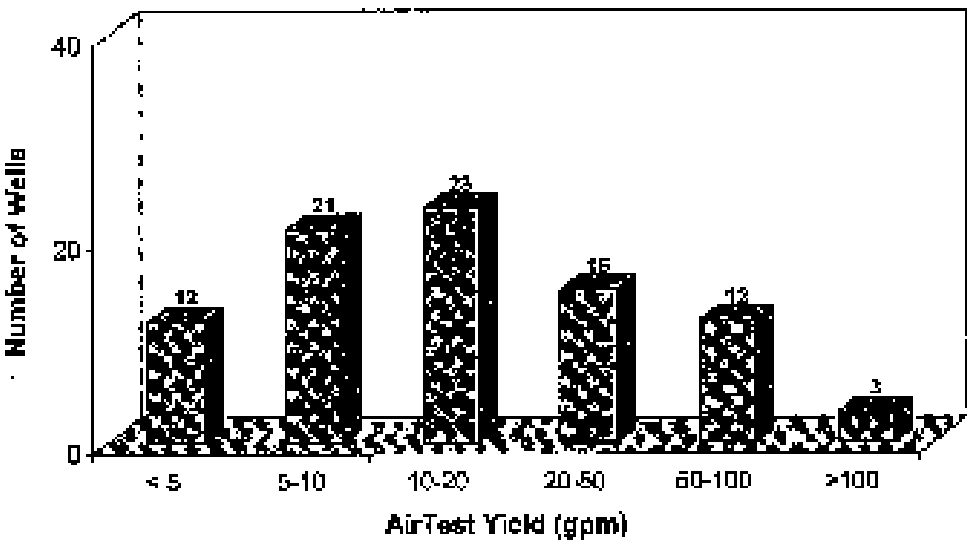


FIGURE 9 - DEPTHS AND AIRTEST YIELDS OF WELLS IN ROAD 400 - ROAD 415 SUBAREA

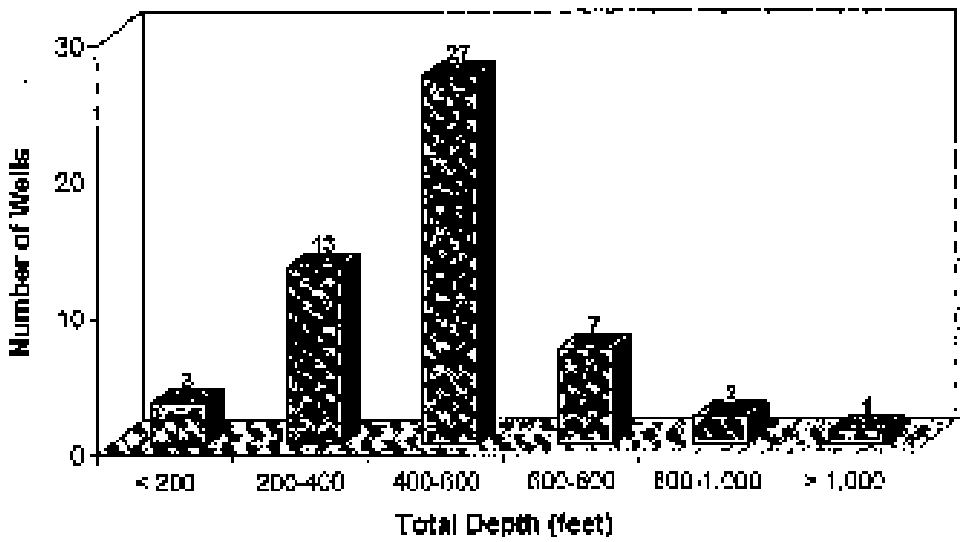

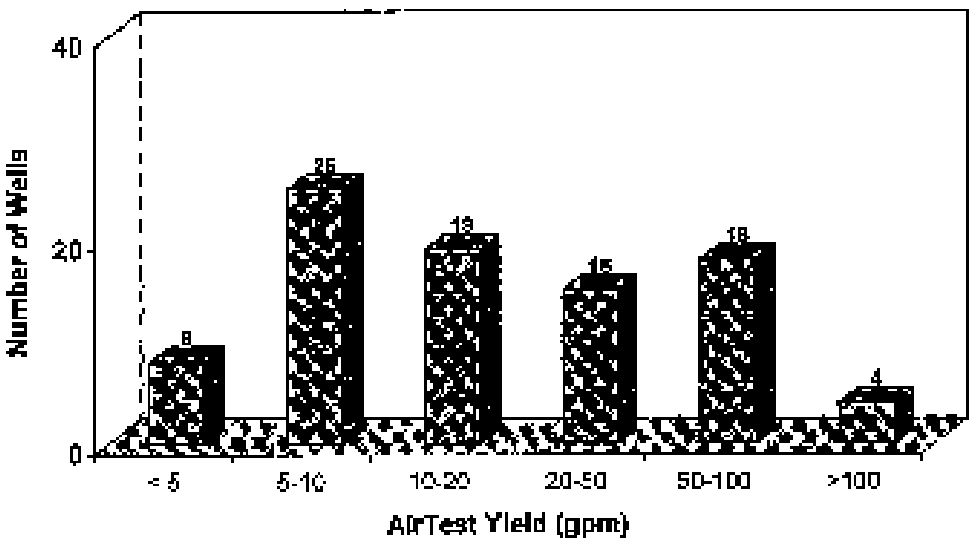

FIGURE 10 - DEPTHS AND AIRTEST YIELDS OF WELLS IN ROAD 416 SUBAREA

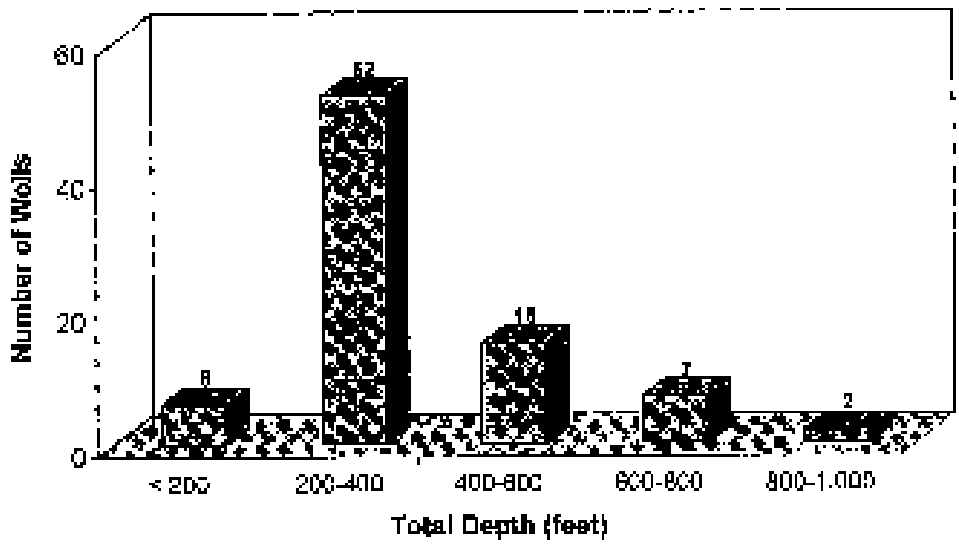
area. Figure 11 shows depths and airtest yields of these wells at the time of drilling. Most of these wells ranged from 200 to 600 feet in depth. Airtest yields for 92 percent of the wells exceeded 5 gpm. Yields for two-thirds of these wells exceeded 10 gpm.

WATER LEVELS

The Chukchansi Indians installed continuous water-level recorders in three of the Casino Wells (No. 1, 2, and 3). Records for these are available since September 2003. In Fall 2004, KDSA commenced a water-level measurement program to supplement these measurements in the Picayune Rancheria vicinity. Included were:

1. Other wells at the Rancheria.
2. A number of private wells that had reportedly gone dry due to pumpage of the Casino wells. These wells were north or northwest of the Casino on the north side of Road 417.
3. Other wells in the area, including numerous water-system and private wells. These wells were primarily within about a mile of the Casino.

As part of the present evaluation, a water-level measurement program was commenced in the Coarsegold area in late 2006. By Summer 2007, a total of 52 wells were being measured on a monthly basis. A comprehensive round of measurements was made in July 2007. Measurements continued through November 2007. Water-level measurements for wells in the Coarsegold area during 2006-07 are provided in Appendix D.



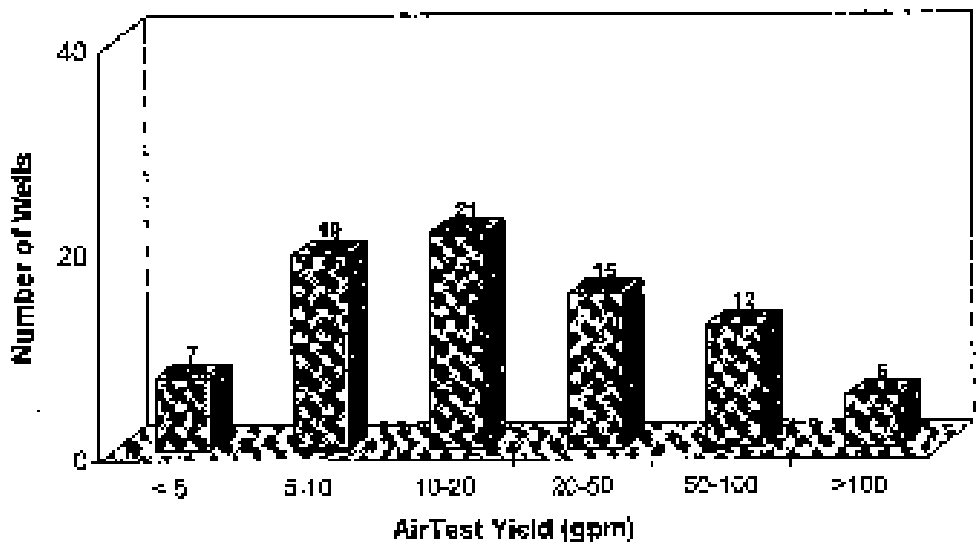


FIGURE 11 - DEPTHS AND AIRTEST YIELDS OF WELLS IN PICAYUNE RANCHERIA SUBAREA

Previous Water-Level Maps

Several water-level elevation maps were available for part of the Coarsegold area. The first map was prepared by Kenneth D. Schmidt (1972) for the Yosemite Lake subdivision. In 1972, most of the Yosemite Lakes wells were in Long Hollow and no deeper than about 400 feet. Water-level elevations ranged from about 1,150 feet to 1,300 feet above mean sea level, and the direction of groundwater flow was to the southwest. Schmidt noted that these elevations, when projected southeast to Coarsegold Creek, were nearly coincident with the creek channel elevations. In 1997, Schmidt mapped water-level elevations for the deeper Yosemite Lakes wells (i.e., more than 900 feet deep). Water-level elevations for these wells ranged from about 1,220 feet at Well 41-A (one of the southwesternmost deep wells) to about 1,270 feet at Well 31-A, the most northeasterly well (except for Well 45-A). A southwestern direction of groundwater flow was also indicated for the deep groundwater. These elevations were generally the same or higher than those in shallow wells in 1972. Well No. 45-A is located on Revis Mountain and had an anomalously high water level (several hundred feet higher than for other deep wells). In 1997, water-level elevations for wells less than 700 feet deep in or near Long Hollow usually ranged from about 1,030 to 1,210 feet. A southwesterly direction of groundwater flow was indicated for these wells.

MDSA (2005) provided a water-level elevation map for the Picayune Rancheria-Indian Lakes area for Fall 2004. Groundwater was generally flowing from high topographic areas toward Coarsegold Creek. However, there were two localized water-level depressions. One was beneath the Indian Lakes well field and the other beneath the Chukchansi Casino well field.

Water-Level Elevations and Direction of Groundwater Flow (July 2007)

Table 7 shows water-level data for wells in the Coarsegold area in July 2007. Figure 12 shows water-level elevations and the direction of groundwater flow in July 2007. In the Mudge Ranch subarea, groundwater was flowing to the west toward Coarsegold Creek. In the Coarsegold subarea, groundwater was flowing toward Coarsegold Creek from both sides, and the creek was indicated to be a location of groundwater discharge. In the Road 416 subarea, groundwater was flowing primarily to the south and toward Coarsegold Creek. The creek was also indicated to be a location of groundwater discharge in this subarea. In the Picayune Rancheria vicinity, groundwater was generally flowing to the west, and there were two water-level depressions. The easterly was around the Indian Lakes well field and the westerly was around the Casino. The lowest water-level elevations in the Coarsegold area (less than 1,530 feet) were near Coarsegold Creek, west of Highway 41. The highest water-level elevations (greater than 3,100 feet) were in

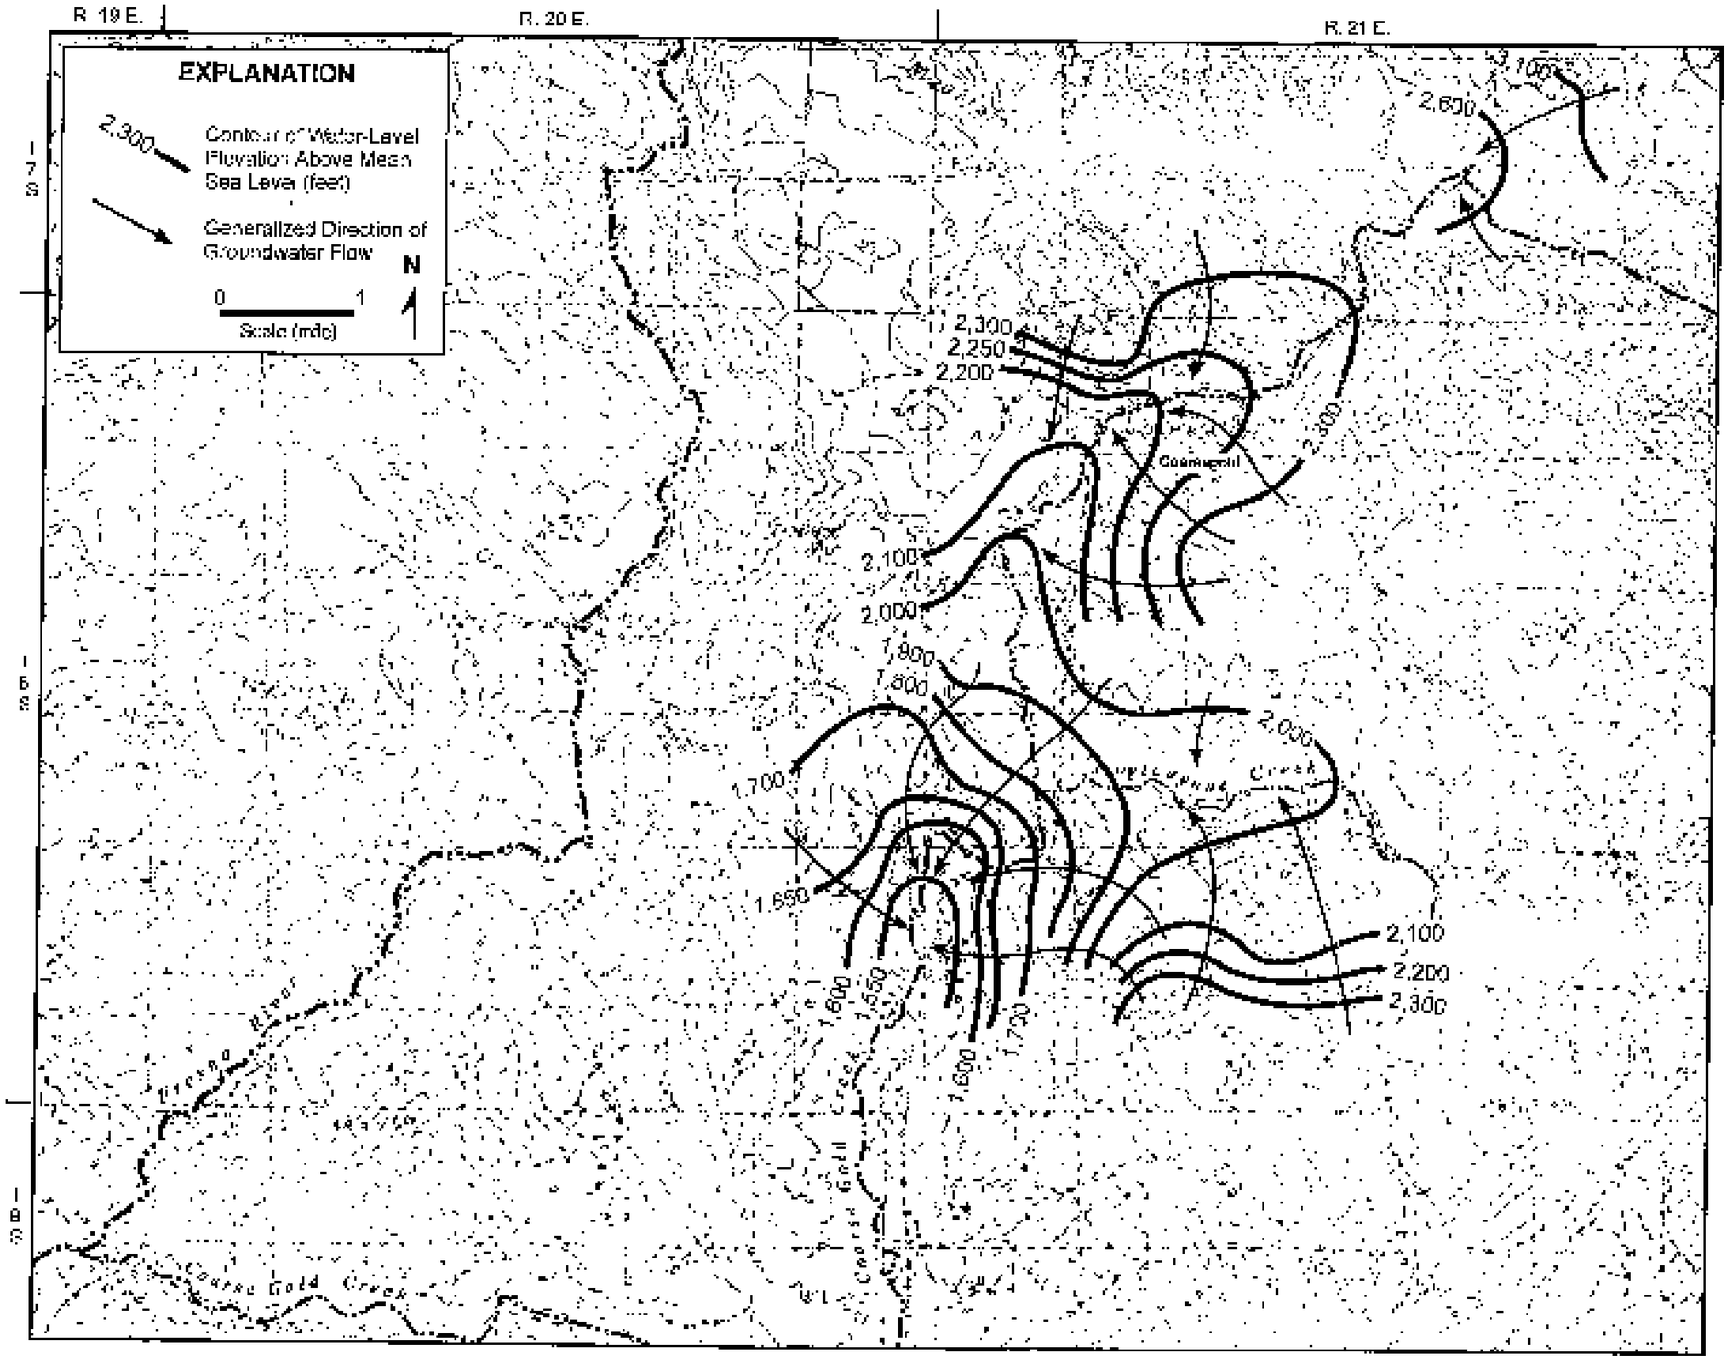

FIGURE 12-WATER-LEVEL ELEVATIONS AND DIRECTION OF GROUNDWATER FLOW IN THE COARSEGOLD AREA IN JULY 2007

the Mudge Ranch area.

Water-Level Trends

Figure 13 shows the locations of subareas with water-level hydrographs in various parts of the Coarsegold area. Area I is the Mudge Ranch subarea and Area II is the Coarsegold subarea. Area III is the Road 416 subarea. Area IV is generally west of the Picayune Rancheria. Area V is the Indian Lakes-Quartz Mountain area. Besides water-levels, monthly precipitation at the Coarsegold Ranger Station is also shown on the hydrographs. Records are not available for August, October, and November.

Figure 14 shows water-level hydrographs for four wells in the Mudge Ranch subarea. Water-level measurements in this subarea commenced in March 2007. Wells with deeper water levels are generally in higher topographic areas or are relatively deep. Since March 2007, water levels in these wells have slightly fallen.

Figure 15 shows water-level hydrographs for seven wells in the Coarsegold subarea. Water-level measurements in this subarea also began in March 2007. Depth to water has been less than 100 feet in water from four of the wells. The deeper water levels are also for wells in higher topographic areas or for deeper wells. Water levels in these wells also slightly fall through November, in the absence of significant precipitation. The water level in one well rose after mid-March 2007, likely due to recharge from precipitation in February 2007.

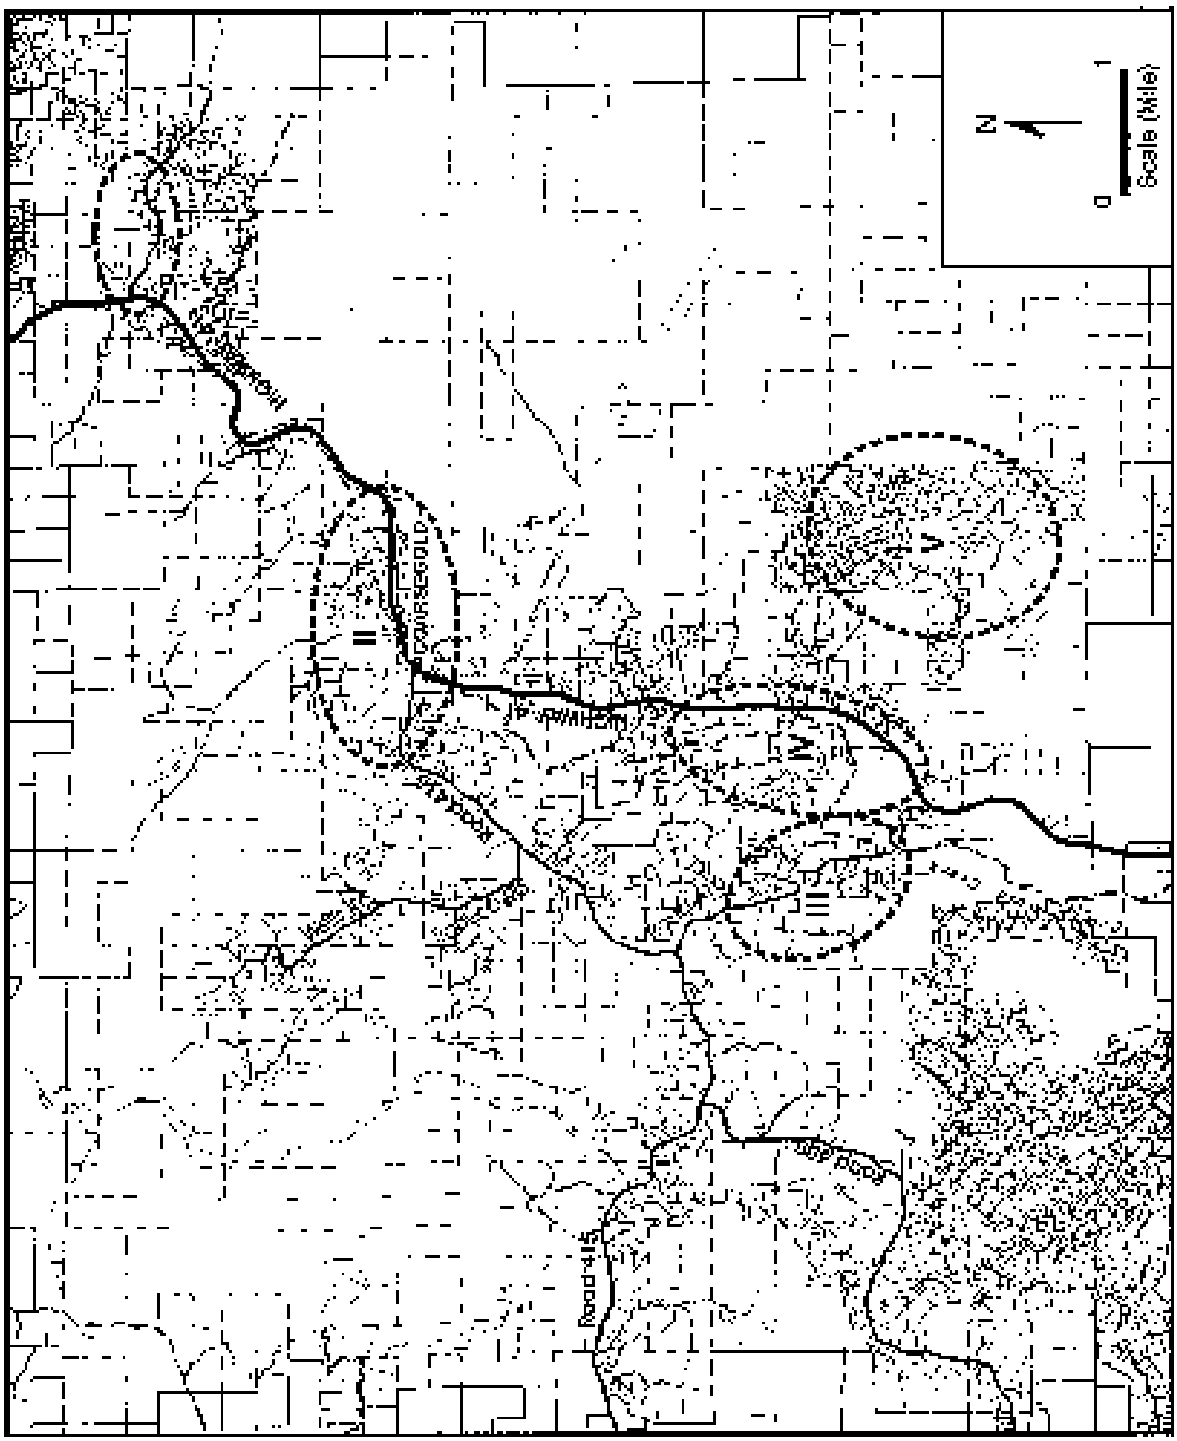

FIGURE 13 - LOCATIONS OF SUBAREAS WITH WATER-LEVEL HYDROGRAPHS

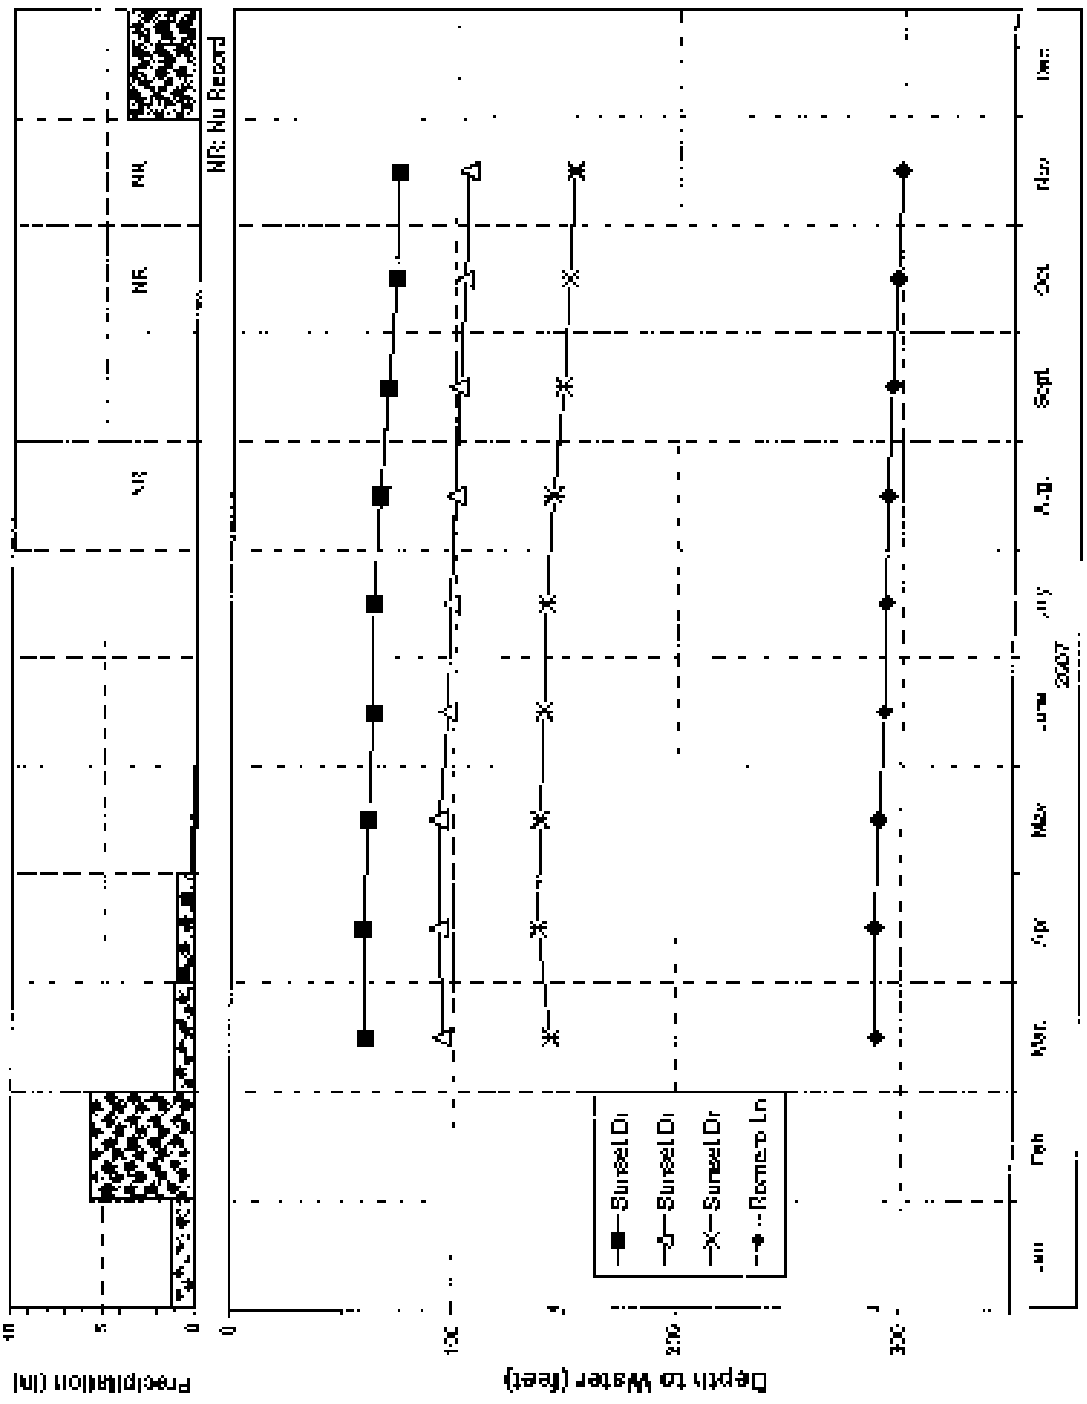

FIGURE 14 - WATER-LEVEL HYDROGRAPHS FOR WELLS IN THE MUDGE RANCH SUBAREA

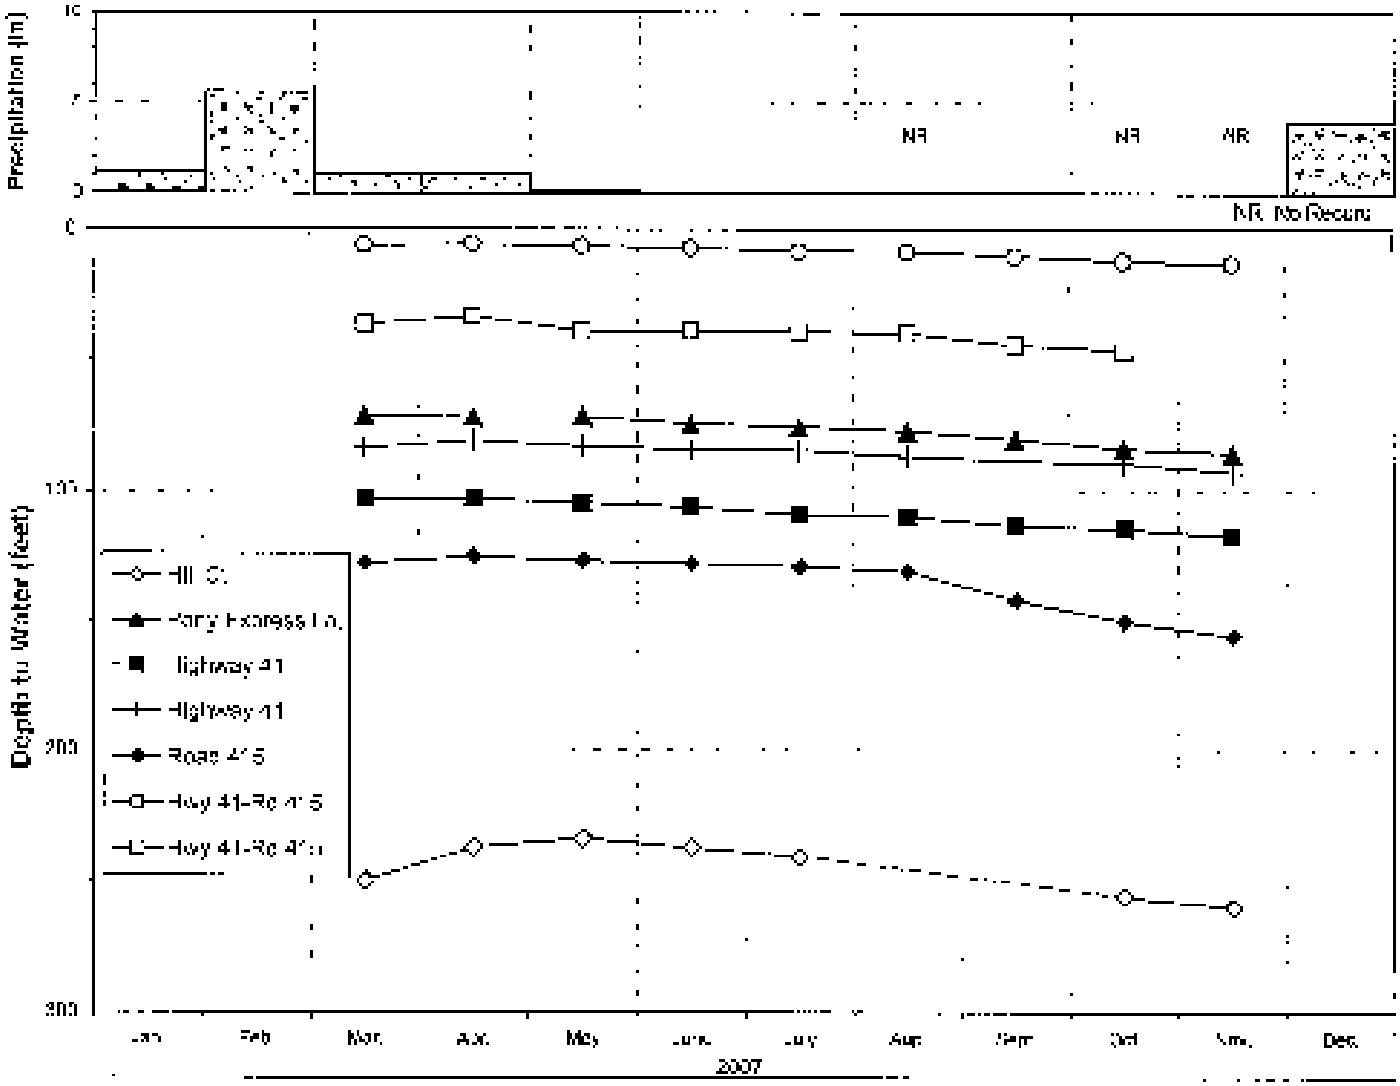

FIGURE 15 - WATER-LEVEL HYDROGRAPHS FOR WELLS IN THE COARSEGOLD SUBAREA

Figure 16 shows water-level hydrographs for eleven wells in the Road 416 subarea. Water levels in this subarea commenced in December 2006. Water levels in wells in this subarea generally did not rise following the December 2006 precipitation. In contrast, all wells in this subarea rose following the February 2007 precipitation. The same trend was also observed in the North Fork area. Much of the December precipitation likely went to satisfy a soil moisture deficiency due to a lack of precipitation prior to December. Water levels in all of the wells fell slightly after April and through November. Overall, water levels in wells in this subarea have been relatively stable. This trend has also been observed in the North Fork area for the same time period.

Figure 17 shows water-level trends for wells in the area west of the Picayune Rancheria, including Sunset Ridge. Water-level measurements in most wells in this area commenced in January 2007 for this program. However, additional measurements for a number of wells in this area are available for 2004. These earlier measurements were done as part of the hydrogeologic evaluation of the Picayune Rancheria vicinity (KDSA, 2005). Water level hydrographs for these wells are provided in Appendix E. Water levels in several wells in this subarea rose following the February 2007 precipitation. Water levels in most wells in this area fell after March and through November, probably due to increased pumping.

Figure 18 shows water-level hydrographs for six wells in the

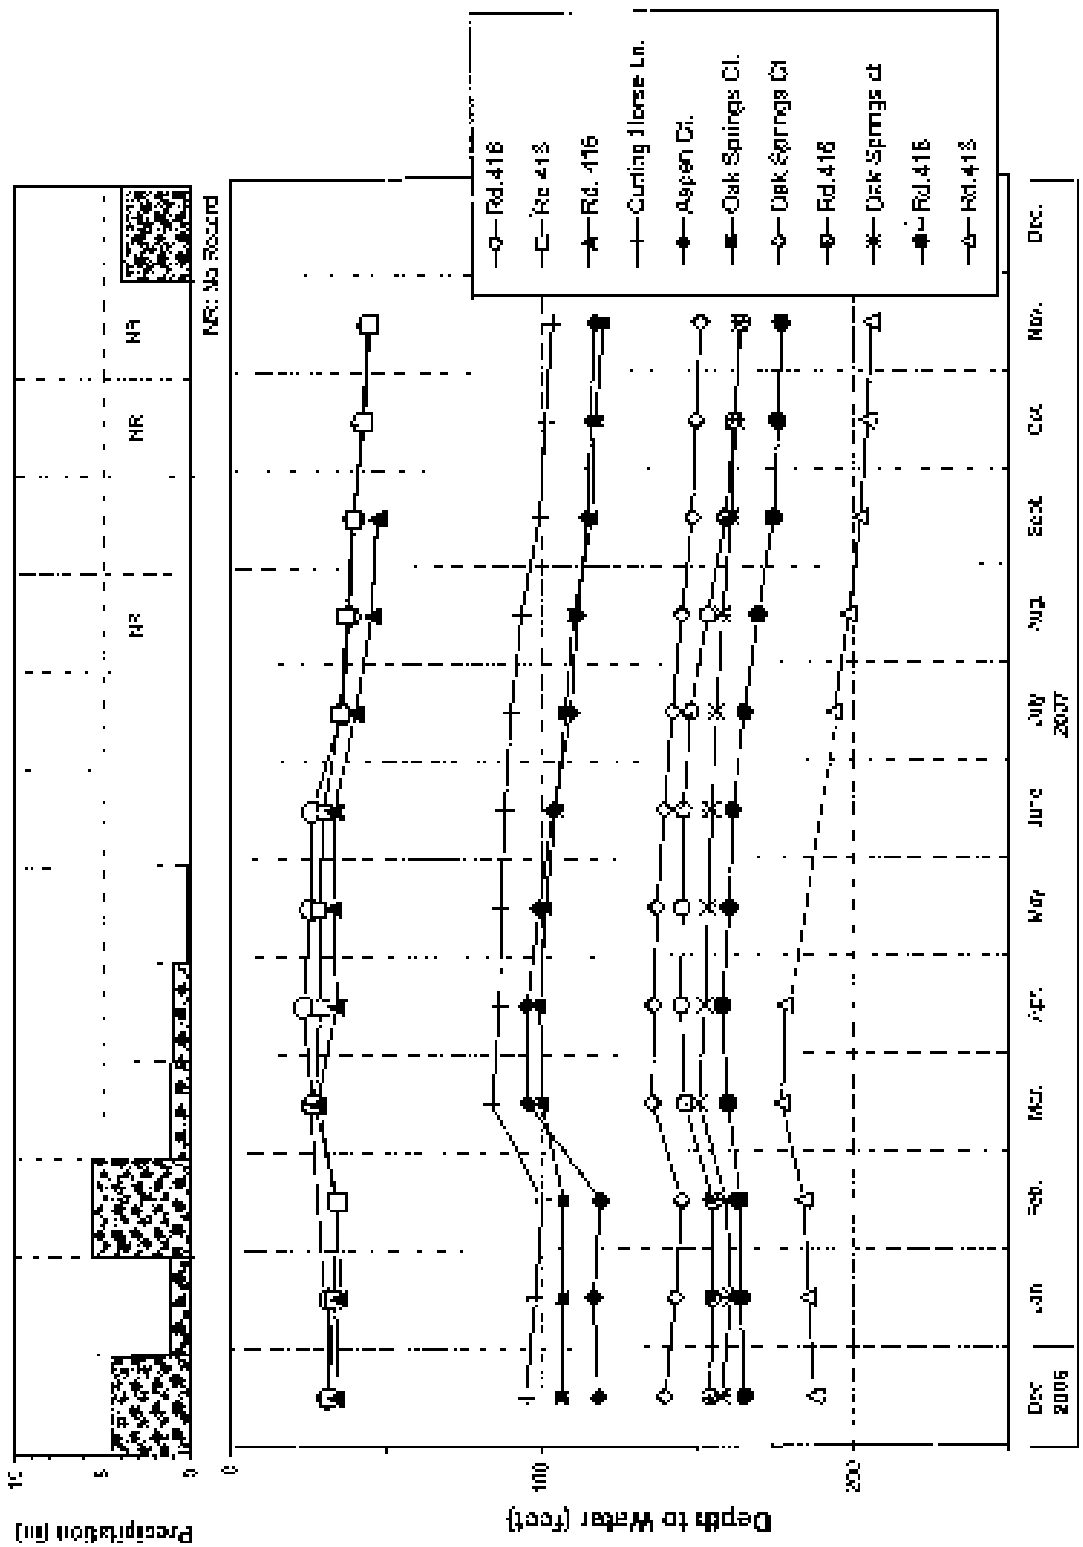

FIGURE 15 - WATER-LEVEL HYDROGRAPHS FOR WELLS IN THE ROAD 416 SUBAREA

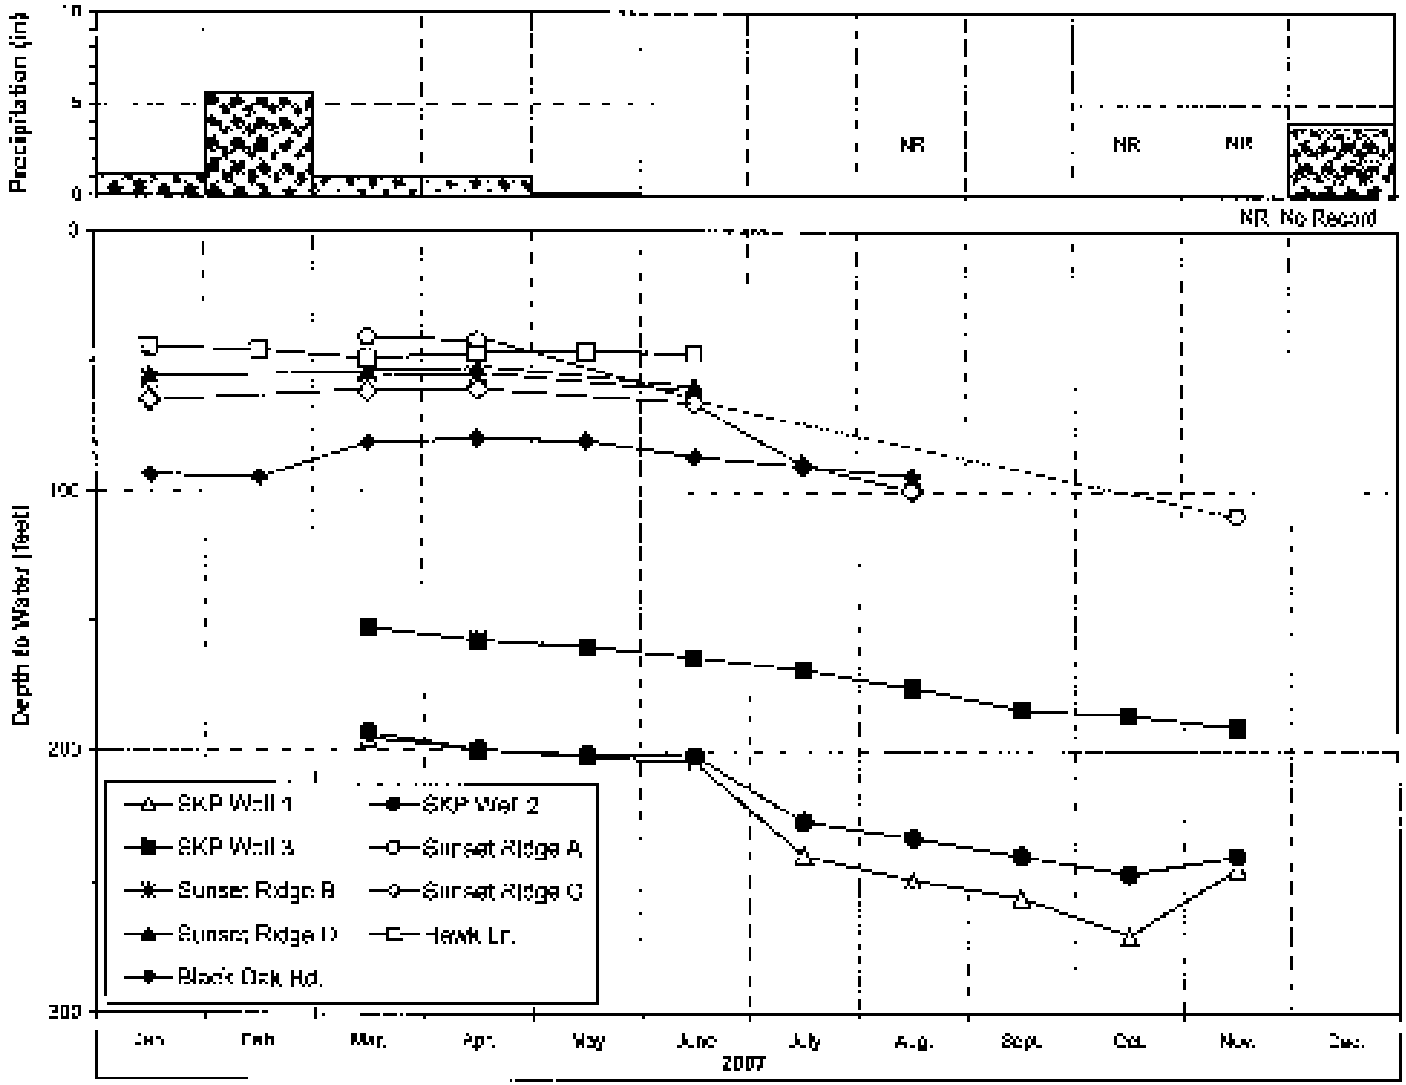

FIGURE 17 - WATER-LEVEL HYDROGRAPHS FOR WELLS WEST OF THE PICAYUNE RANCHERIA

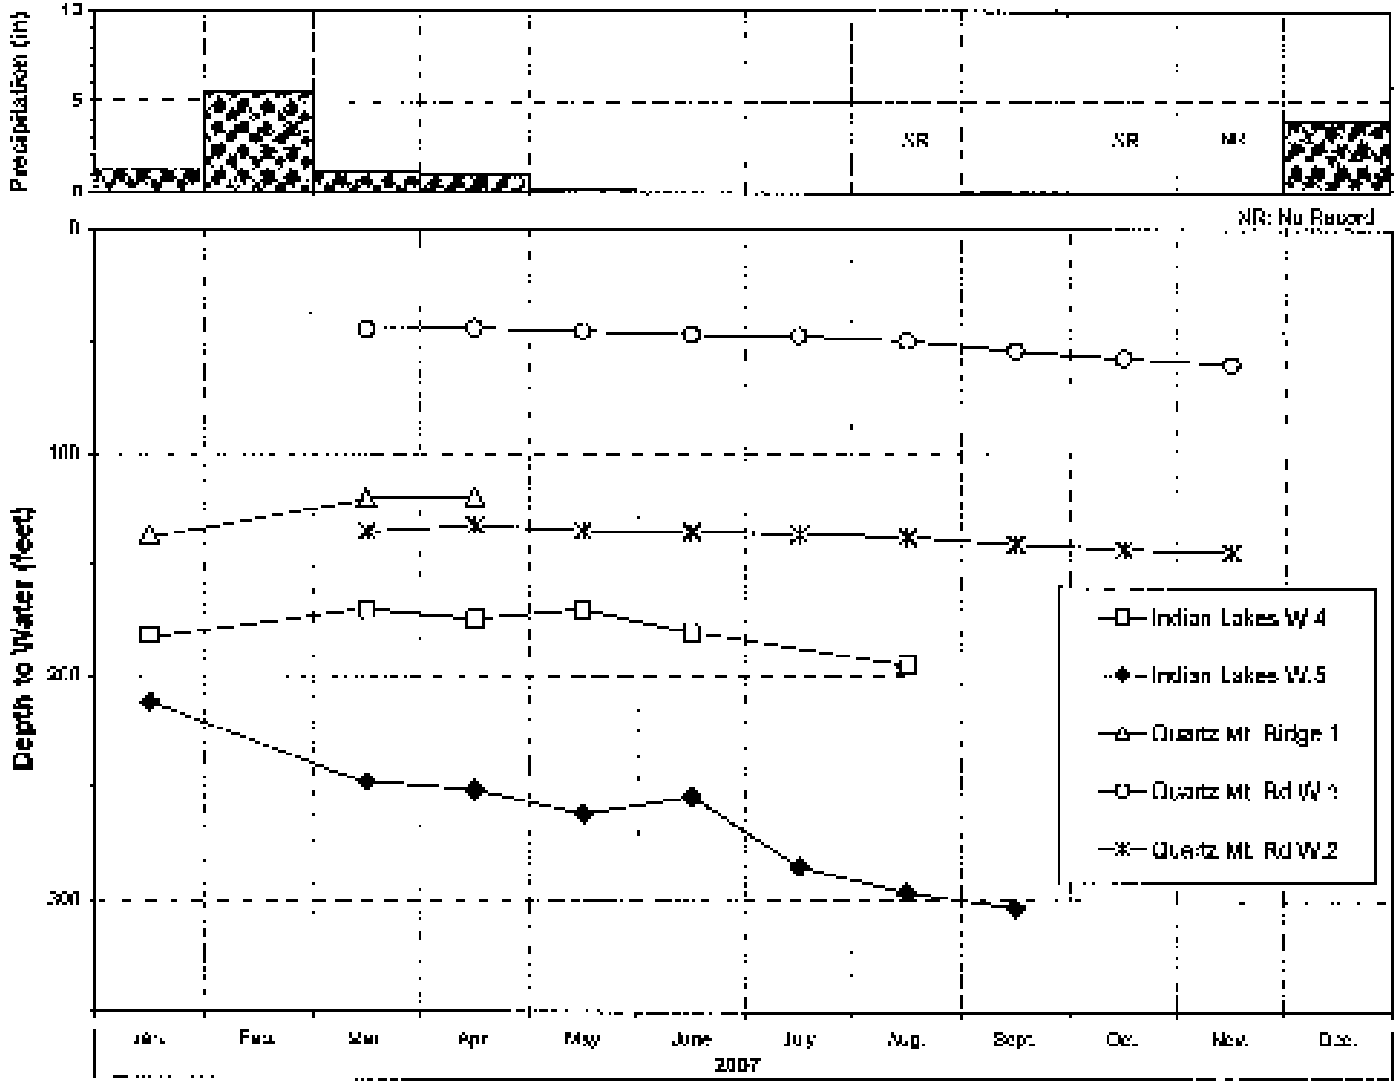

FIGURE 18 - WATER-LEVEL HYDROGRAPHS FOR WELLS IN THE INDIAN LAKES - QUARTZ MT. AREA

Indian Lakes and Quartz Mountain water systems. Measurements of these wells for this program began in January 2007. Water levels in at least two of these wells rose following the February 2007 precipitation. Water levels in these wells fell after April through November. Wells such as Indian Lakes No. 5 were influenced by increased summer pumping. Measurements for wells in this area are also available for 2004, due to the previous evaluation, and are provided in Appendix E.

Picayune Rancheria Area

Water-level hydrographs for selected wells for 2004-07 are provided in Appendix E. Water levels in most wells in 2007 were near or shallower than levels in 2004.

Figure 19 shows water-level hydrographs for the Casino wells, based on the transducer measurements for 2003-07. Because of their continuous nature, these are considered some of the most valuable water-level measurements for the Coarsegold area. One can compare seasonal high water levels (normally in spring) from year to year, and also the lows (normally in the late fall). For Well No 3, transducer measurements aren't available after Spring 2005. Records for Wells No. 1 and 2 are available for most of the period. For Well No. 1, seasonally shallow levels were progressively higher each spring. For Well No. 2, seasonal deepest water levels were deepest in Fall 2014 and shallowest in 2007.

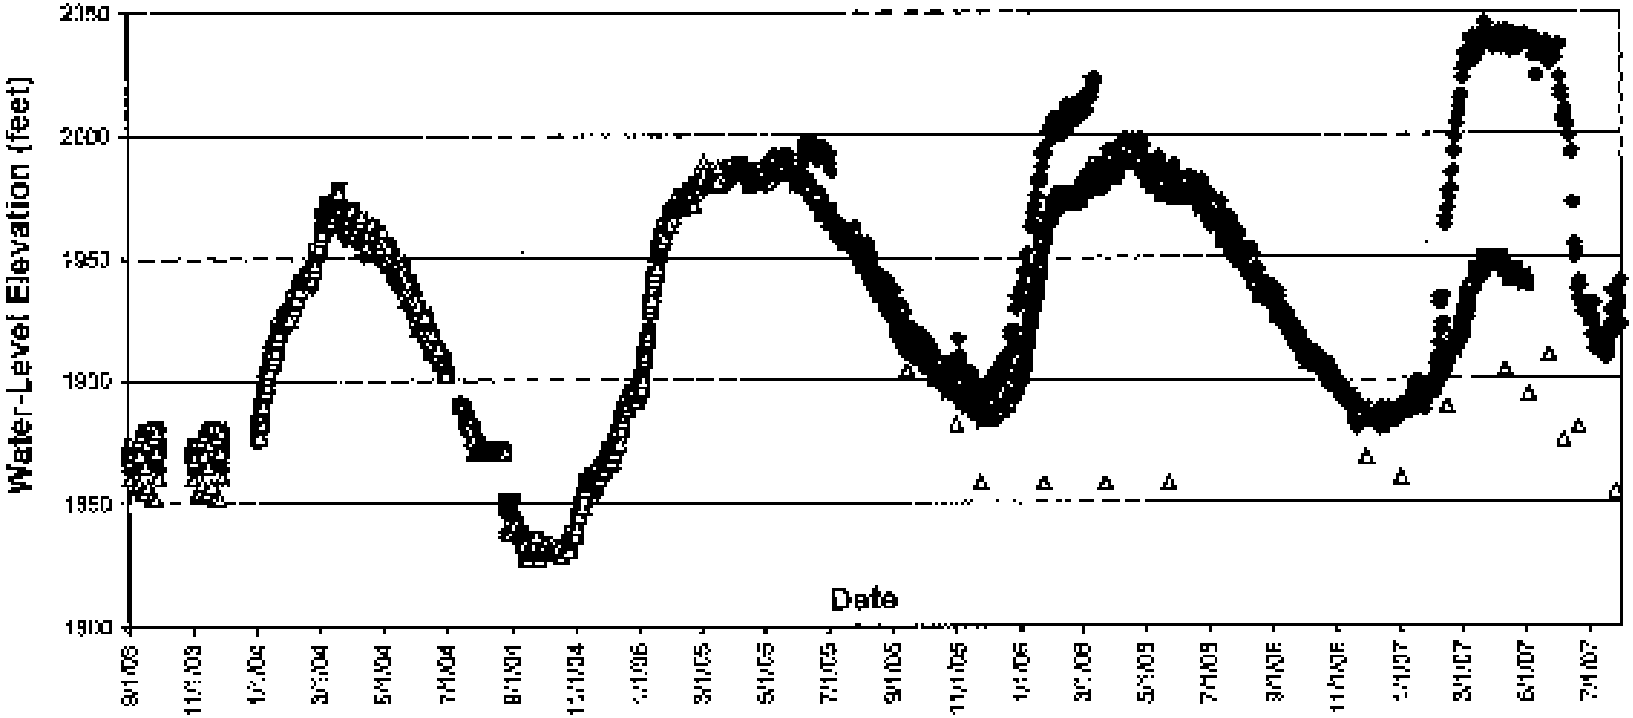

FIGURE 19 - WATER-LEVEL HYDROGRAPHS FOR PICAYUNE RANCHERIA WELLS

PUMPAGE

Large Water Systems

Pumpage is measured for large systems and values for 2006 are:

System	Pumpage (acre-feet)
Meadow Springs Ranch	24
Sunset Ridge	20
Coarsegold Highlands	9
Indian Lakes	270
Quartz Mountain	90
Casino	62
Yosemite Lakes	790

The total pumpage for these systems was thus 1,265 acre-feet in 2006. In addition, there was an estimated 110 acre-feet pumped in Yosemite Lakes for the golf course and lakes.

Small Water Systems

Pumpage for small systems in 2006 was estimated, based on a similar water use per lot as for large systems, as follows:

System	Pumpage (acre-feet)
The Village	13
Oak Creek MHP	50
Bluff Drive W.C.	4

The total pumpage for these systems was thus 67 acre-feet in 2006.

Individual Wells

As part of this evaluation, the number of developed lots in the Coarsegold area that aren't on water systems was estimated. Recent aerial photos were used, along with County records on developed lots. Following were the numbers of developed lots that were not on water systems in the five subareas, as of 2006.

Mudge Ranch Subarea	192
Coarsegold Subarea	201
Road 415-Trabuco Subarea	177
Road 415-Road 400	160
Road 416	130

There are five other areas of relatively dense development in the Coarsegold. Area A is northwest of the Road 415-Trabuco subarea. Area B is primarily between Sunset Ridge and Coarsegold, in the area between Highway 41 and Road 415. Area C is generally north of Yosemite Lakes along Road 400. Area D is generally west of Indian Lakes and Quartz Mountain. The number of developed lots that were not on water systems in these areas as of 2006 were:

Area A	112
Area B	183
Area C	69
Area D	43

Adding in about 130 lots in less developed areas (ten acre or smaller lots), the total number of developed lots not on water

systems as of 2006 was about 1,400. An average water use of 0.6 acre-feet per year is used for these lots, based on the average use in water systems in the Coarsegold area. The estimated water use for these undeveloped lots in 2006 was thus about 840 acre-feet. The total pumpage in the Coarsegold area is estimated to have been about 2,300 acre-feet in 2006.

AQUIFER TESTS

Picayune Rancheria

Kleinfelder, Inc. (2004) reported on the results of a four-day pump test conducted on Casino Well No. 2 during March 18-22, 2003. This test was done after a number of private domestic wells north of the Casino were reportedly dried up due to pumping of Casino Well No. 2 for construction. Well No. 2 is 382 feet deep and was pumped continuously at about 100 gpm for the test. Water levels in Tribal Well No. 4 (200 feet deep) and six private domestic wells were also measured during the test. Depths of the private domestic to the north wells that were measured ranged from about 160 to 250 feet.

Transmissivity is a parameter that can be used to estimate amounts of groundwater flow. Using the transmissivity and storage coefficient, one can predict the drawdowns in wells due to pumping of one or more other wells. Long-term drawdown measurements for the pump test on Well No. 2 indicated an aquifer transmissivity of

730 gpd per foot. Recovery measurements for the pumped well provided the best estimate of aquifer transmissivity, and these indicated a value of 1,550 gpd per foot. A storage coefficient of about 0.0001 was determined from measurements in one of the observation wells, indicative of confined conditions.

The largest drawdowns were observed in wells north or northwest of Well No. 2. These wells apparently tapped the same fracture zone as that tapped by Well No. 2. Drawdowns in six of the observation wells ranged from about 11 to 42 feet during the test. The greatest drawdown was in the Hayes Well (215 feet deep), which had a drawdown of only about 11 feet less than the pumped well itself. Except for this well, drawdowns in the private domestic wells during the test were less than 18 feet. Considering seasonal water-level fluctuations, there was essentially no drawdown in Tribal Well No. 4 during the test.

Meadow Springs Ranch

KDSA (2003) reported on the results of eleven-day pump tests that were conducted in September-October, 2002 for two wells at the Meadow Springs Ranch subdivision. Well No. 1 was drilled in March 1994 to a depth of 1,200 feet. Well No. 1 obtained most of its production from fractures between 900 and 1,090 feet in depth. Well No. 2 was drilled in April 1994 to a depth of 494 feet. Well No. 2 obtained most of its production from about 490 to 495 feet in

depth. Well No. 1 was pumped at an average rate of 64 gpm and Well No. 2 was pumped at the same time at about 270 gpm. The combined long-term yields of the two wells was estimated to be about 280 gpm. Recovery measurements for the tests indicated that the aquifer transmissivity ranged from 5,000 to 5,700 gpd per foot.

Yosemite Lakes Subdivision

Schmidt (1972) reported on a 14-day pump test that was conducted on Well 29A during March-April, 1970. Most of the Yosemite Lakes wells at that time ranged from about 150 to 400 feet deep. Well 29A was 159 feet deep. The average pumping rate was 133 gpm. An average transmissivity, based on measurements in six observation wells, was 2,300 gpd per foot and the average storage coefficient was 0.00003. In 1995, ten-day pump tests were conducted on Wells 29-A (which had been deepened to 207 feet), No. 44-A, No. 46-A, and No. 47-A. However, transmissivity wasn't determined for these tests.

GROUNDWATER QUALITY

In this section, the geographic distribution of several key constituents in the groundwater is first discussed. This is primarily based on Summer 2007 sampling of water from a number of individual wells, supplemented by recent analyses of water from water system wells. This is followed by a discussion of the quality of the water from water system wells. Appendix F contains

laboratory reports for analyses of water from wells in the Coarsegold area.

Geographic Distribution

Total Dissolved Solids

Water samples were collected from 20 individual wells in the areas outside of water systems in May 2005. Water from another 10 individual wells was sampled in later July 2007. Total dissolved solids concentrations in most of these wells ranged from about 180 to 310 mg/l. Water from one well on Road 415 had a TDS concentration of 600 mg/l, which appears to be unusual for the area.

Nitrate

Nitrate concentrations in water from wells sampled during 2007 were all less than 27 mg/l, below the maximum contamination level (MCL) of 45 mg/l. Except for four of these wells, nitrate concentrations were 6 mg/l or less, well below the MCL. Water from 12 of the individual sampled wells had nitrate concentrations less than 2 mg/l.

Iron and Manganese

High iron and manganese concentrations have been common in water from a number of wells in the Coarsegold area. Figure 20 shows the locations of two areas where iron concentrations exceeded the MCL of 0.5 mg/l in well water in recent years. The largest

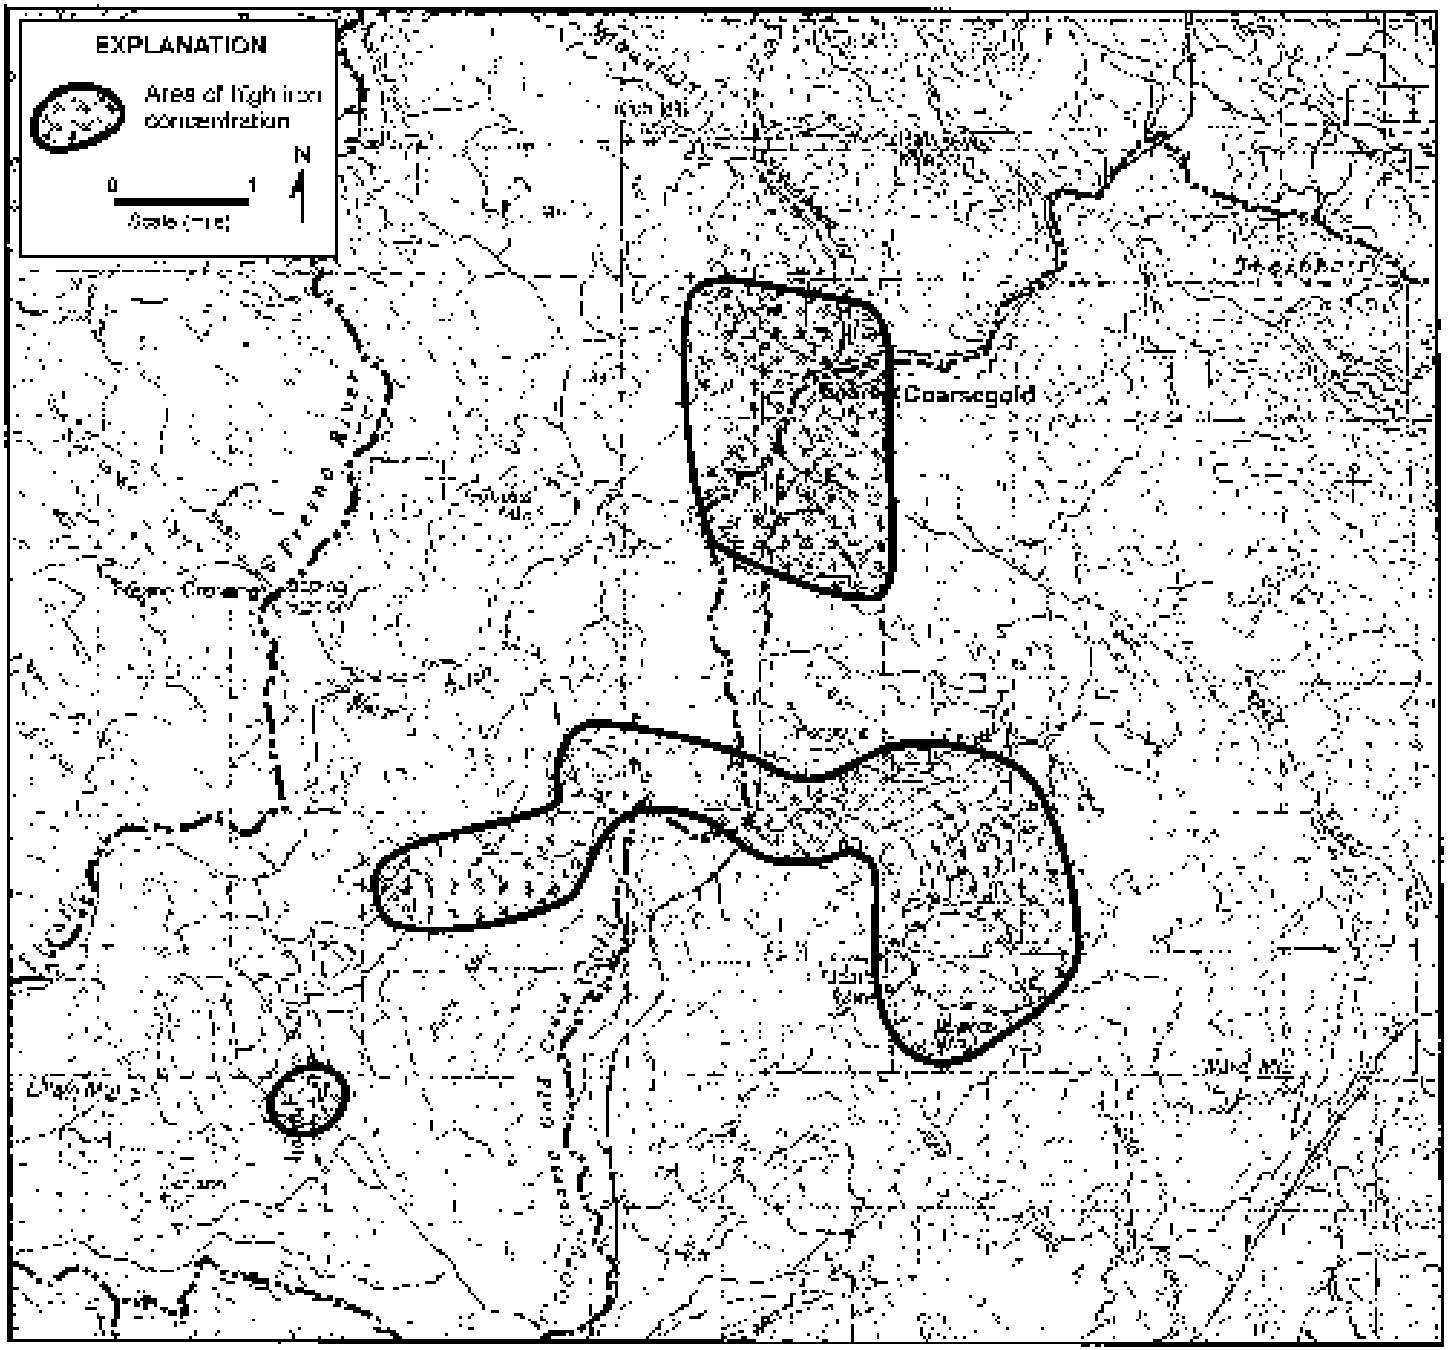

FIGURE 20 - LOCATIONS OF HIGH IRON CONCENTRATIONS IN WATER FROM WELLS IN THE COARSEGOLD AREA

area extended through Quartz Mountain, Indian Lakes, the Picayune Rancheria, and to the west, including the Sunset Ridge water system. The second area was in Coarsegold and Meadow Springs Ranch, where water from five wells had iron concentrations exceeding the MCL. Water from at least two wells in the Yosemite Lakes water system had iron concentrations exceeding the MCL.

Figure 21 shows areas where manganese concentrations in water from wells exceeded the recommended MCL of 0.05 mg/l. Four areas were present, including in or near the two areas where high iron concentrations were present. A fairly large area of high manganese concentrations was present in part of the Yosemite Lakes subdivision, and many wells produced water with manganese concentrations exceeding the MCL. Most of the wells with high manganese concentrations were in or east of Long Hollow. In addition, one well in the Mudge Ranch subarea had water with a manganese concentration exceeding the MCL.

Water in many public water system wells has been treated for removal of iron and/or manganese for many years.

Arsenic

Arsenic concentrations in the individual wells sampled were below the new MCL of 10 ppb, except for three wells. One of these (10 ppb) was in Mudge Ranch and the other two (14 to 17 ppb) were in the Road 416 area.

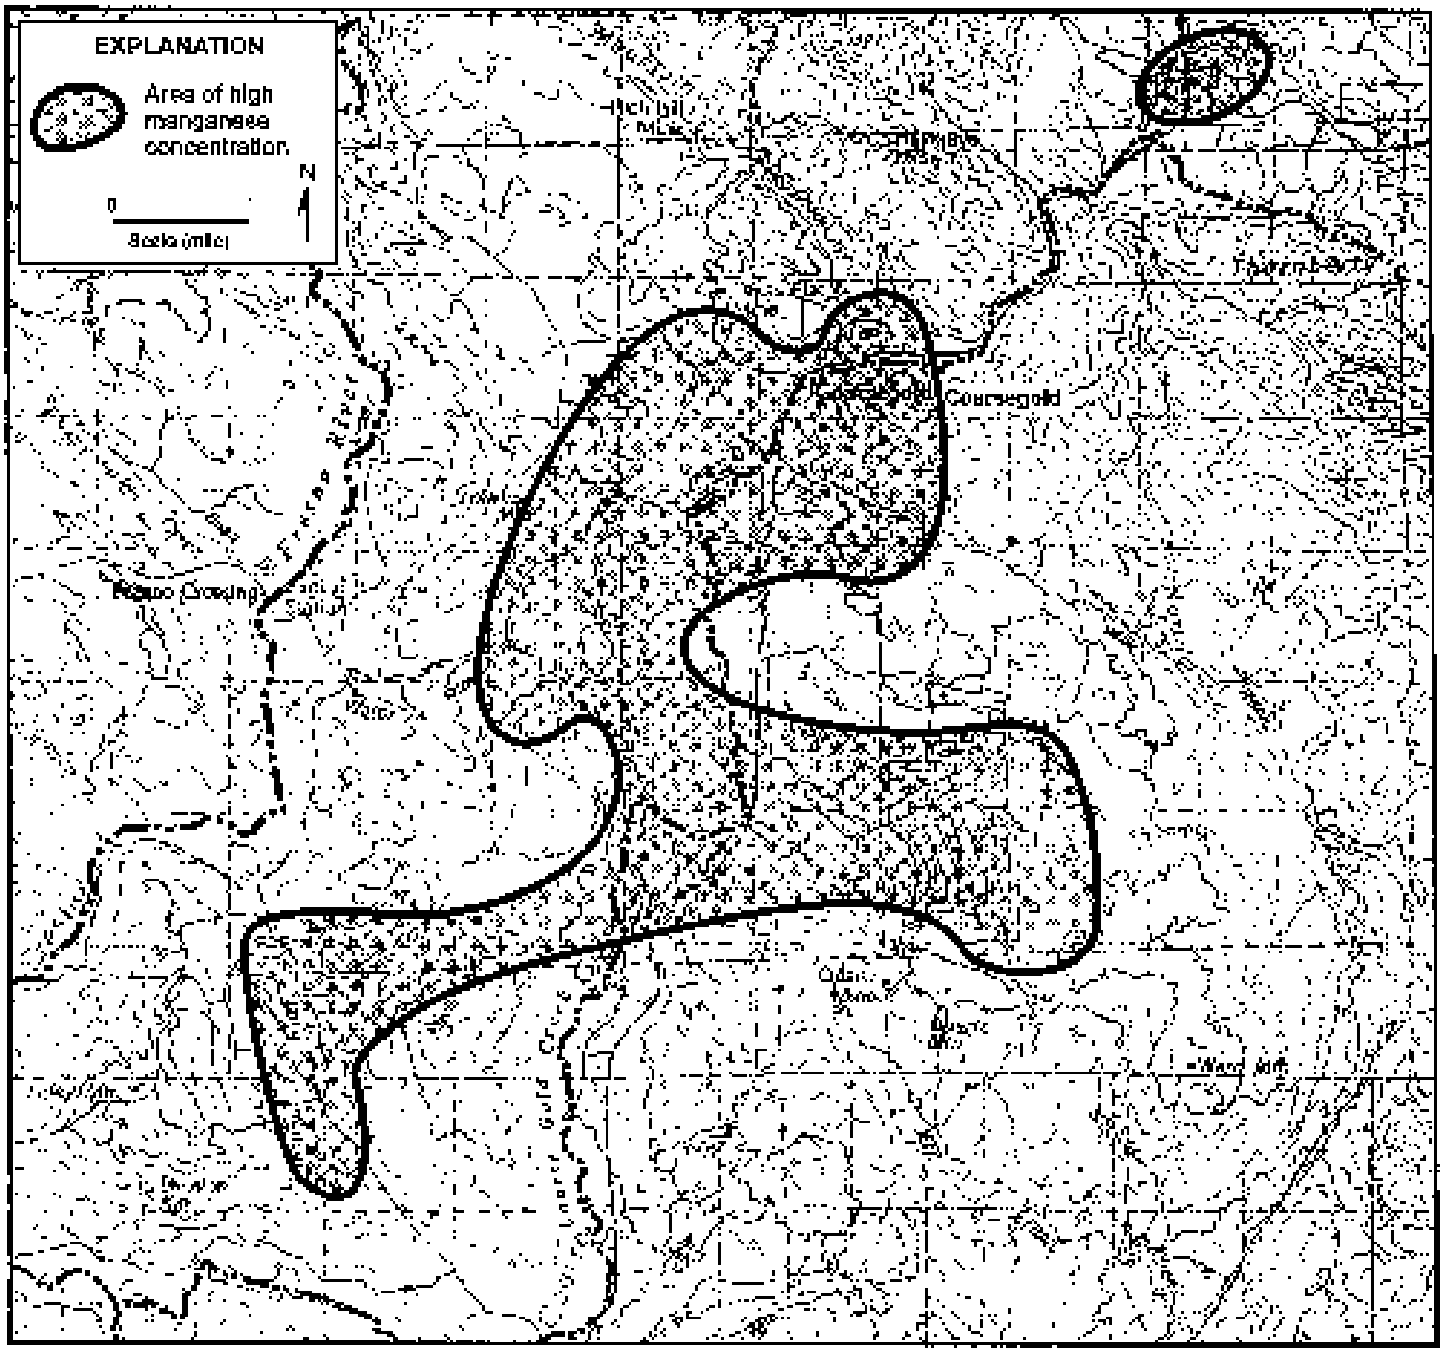

FIGURE 21 - LOCATIONS OF HIGH MANGANESE CONCENTRATIONS IN WATER FROM WELLS IN THE COARSEGOLD AREA

Uranium

Alpha activity is an indicator of uranium activity, and is a cheaper test to perform than is uranium. Water from four individual wells that were sampled in May 2007 and two Yosemite Lakes wells (37-A and 46-A) had alpha activities near or exceeding the MCL of 15 picocuries per liter. Figure 22 shows the general area where water from wells had alpha activities exceeding the MCL of 15 picocuries per liter. Three wells in the area north of the Yosemite Lakes subdivision, one well along Road 416, one well in the Picayune Rancheria area, and one well in Yosemite Lakes had alpha activities exceeding the MCL of 15 picocuries per liter in recent years.

Water System Wells

Picayune Rancheria

Kleinfelder, Inc. (2004) reported on the quality of water from Casino Wells No. 1, 2, and 3 as of 2003 (Table 8). TDS concentrations ranged from 181 to 210 mg/l and nitrate concentrations were 2 mg/l or less. Iron concentrations in water from Wells No. 1 and 2 ranged from 0.3 to 0.57 mg/l, compared to the recommended MCL for drinking water of 0.3 mg/l. Manganese concentrations in water from the three wells ranged from 0.05 mg/l to 0.18 mg/l, compared to the MCL for drinking water of 0.05 mg/l. The Tribe has found that iron bacteria have been forming in Well No. 3, causing partial plugging

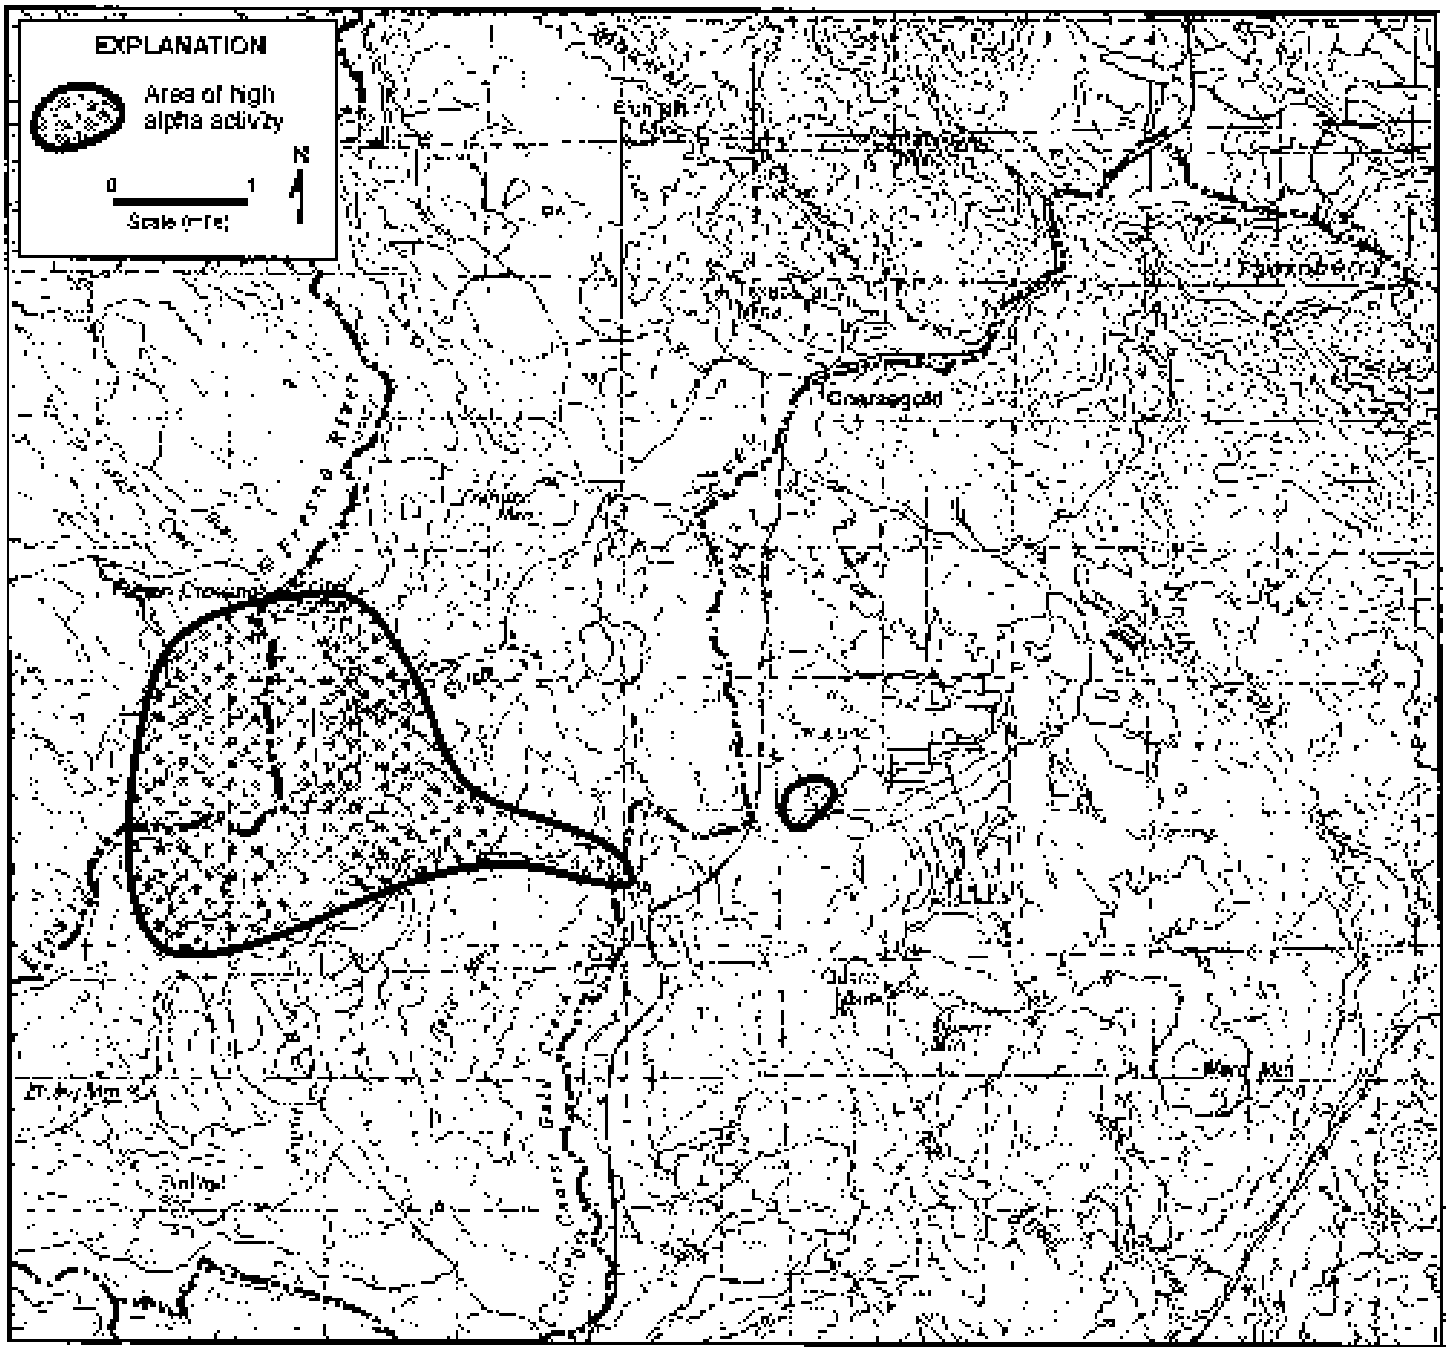

FIGURE 22 - LOCATION OF HIGH ALPHA ACTIVITIES IN WATER FROM WELLS IN THE COARSEGOLD AREA

TABLE 8-CHEMICAL ANALYSES OF WATER FROM CASINO WELLS

Constituent (mg/l)	No. 1	No. 2	No. 3	MCL

Alpha Activity (pc/l)	5.7	4.3	7.6	15
Date	5/30/03	3/20/03	4/7/03	

Analyses from Kleinfelder, Inc. (2004)

of the perforations and a reduction in well yield. Arsenic concentrations in water from these wells ranged from 0.003 to 0.004 mg/l and were well below the new MCL of 10 ppb. Alpha activities ranged from 4.3 to 7.6 picocuries per liter and were well below the MCL of 15 picocuries per liter. Iron and/or manganese concentrations exceeding the recommended MCLs are commonly found in groundwater in the Coarsegold-Yosemite Lakes area. Discolorization, a foul odor, and a bad taste was reported in water from Cardosa Well, north of the Casino. This is evidence for iron bacteria, which could result in plugging of the well and a reduced pumping rate.

Indian Lakes, Quartz Mountain, and Sunset Ridge

TDS concentrations in water from the Indian Lakes and Quartz Mountain wells ranged from 240 to 270 mg/l, and nitrate concentrations were less than 2 mg/l in 2002. Iron and manganese concentrations in the Indian Lakes wells (Table 9) and Quartz Mountain (Table 10) wells exceed the MCLs and the water is treated prior to use. Concentrations of arsenic and alpha activity have been low in water from these wells. The chemical quality of groundwater from the two new Indian Lakes wells is very similar to that from the existing wells. Manganese concentrations have also exceeded the MCL in water from the Sunset Ridge wells (Table 11).

Coarsegold Highlands

wells ranged from 220 to 230 mg/l and nitrate concentrations were less than 2 mg/l in January 2005. Nitrate and arsenic concentrations and alpha activities were well below the respective MCLs. Moderate iron concentrations and manganese concentrations exceeding the recommended MCL have been present in water from the Coarsegold Highlands wells (Table 12), and this water is treated prior to use. Arsenic concentrations and alpha activities in water from these wells have been well below the respective MCLs.

Meadow Springs Ranch

Table 13 contains the results of chemical analyses of water from two wells at the Meadow Springs Ranch system. Nitrate and arsenic concentrations and alpha activities were low, well below the respective MCLs. Iron and manganese concentrations exceeded the MCL, and water from the wells was being treated for iron and manganese removal.

Yosemite Springs Park Utility

Table 14 contains the results of analyses of water from the seven wells that provided much of the pumpage for the system in 2006. TDS concentrations ranged from 180 to 290 mg/l. Nitrate concentrations were less than 3 mg/l in water from all of these wells, well below the MCL of 45 mg/l. Iron concentrations in water from two of the wells (37-A and 45-A) exceeded the recommended MCL of 0.3 mg/l. Manganese concentrations in water from six of these

wells exceeded the recommended MCL of 0.05 mg/l. Manganese treatment of well water has been practiced at Yosemite Lakes for decades. The pH ranged from 6.7 to 8.3 and was lowest in water from Well 37-A. Arsenic concentrations in water from all of these wells were less than the new MCL of 10 ppb. Alpha activities ranged from 0.3 to 14.7 picocuries per liter, less than the MCL of 15 picocuries per liter. Well No. 46-A was on standby, because the uranium concentration exceeded the MCL. Except for this well and Well 37-A, values were less than 9 picocuries per liter. Water from two wells (37-A and 40-A) had detectable MTBE concentrations and was being treated prior to use.

SUMMARY AND CONCLUSIONS

Precipitation on the watershed of Coarsegold Creek is the primary source of recharge to groundwater in the Coarsegold area. Average annual precipitation ranges from less than 16 inches near the confluence of Coarsegold Creek with the Fresno River to about 30 inches at Mudge Ranch. The majority of the precipitation is consumed by evapotranspiration of plants on the watershed, and the remainder runs off as streamflow. Groundwater generally flows toward Coarsegold Creek or the Fresno River. Evapotranspiration is estimated to range from about 14 inches per year near the southwest corner of the Coarsegold area to about 22 inches at Mudge Ranch. Some of the residual between precipitation and evapotranspiration

is available to recharge pumped groundwater.

Water systems are predominant in the south part of the Coarsegold area and individual wells are predominant in the central and northern parts of the area. Depths of some water system wells exceed 1,000 feet. A number of deep wells have been drilled by the Yosemite Spring Park Utility. Two deep wells have been drilled at Indian Lakes, one at the Chukchansi Casino, and one at the Al Miki Ranch. Substantial water production has been found at depths below 700 feet. Relatively large hardrock well yields have been demonstrated at Yosemite Lakes.

Water levels in areas where individual wells are used have relatively small seasonal changes and well interference problems are limited. In contrast, in some areas where large-capacity wells are used, there are seasonal water-level variations of more than 100 feet. In such areas, well interference can be a problem if large-capacity wells are sited too close to other wells. The lateral extent of the cones of depression associated with pumping of deep wells in the Coarsegold area has not been determined. This is important, because pumpage of deep wells could draw groundwater from beneath adjoining lands, and limit future pumping of deep groundwater beneath other lands.

The most limited groundwater available appears to be in the southwest part of the Coarsegold area, where the average annual precipitation is less than about 22 inches. Groundwater recharge

is less in this area because the residual between precipitation and streamflow is less.

Identified groundwater quality problems in parts of Coarsegold area include high iron, manganese, and uranium concentrations. These occurrences are all indicated to due to natural factors.

There is no known stream gaging in the Coarsegold Creek watershed. Streamflow records (particularly during low flow periods) at key locations would provide more understanding of the groundwater. Presently, there has been no need demonstrated for a surface water importation project to the Coarsegold area. Surface water importation to the area and use could be considered in the southwest part of the Coarsegold area, if new dense development is considered in the future. Blackhawk Reservoir has considerable storage space and could possibly be used in that regard.

RECOMMENDATIONS

The former streamgage on Picayune Creek above the confluence with Coarsegold Creek should be re-established. In addition, at least two gaging stations should be developed on Coarsegold Creek. One would be downstream of Blackhawk Reservoir and the other near Coarsegold. A routine water-level monitoring program for wells in the Coarsegold area should be continued, to supplement water-level records for water system wells. Hydrogeologic studies should be required for new subdivisions, as proposed in the Oakhurst Basin

hydrogeologic report (KDSA, 2005). For new individual wells, water samples should be collected for selected constituents, including alpha activity. Individual well owners should be made aware of areas with possible water quality problems. Further studies should be done on the cone of depression due to deep well pumping in systems such as Yosemite Lakes.

APPENDIX D

WATER-LEVEL MEASUREMENTS FOR WELLS IN COARSEGOLD AREA FOR 2006-07

WATER-LEVEL MEASUREMENTS

COARSEGOLD AREA

Park Sierra Dr.

Well head elevation 1,881.2 ft

Distance from M.Pt to G.S 1.0 ft

Date of Measurement	Time	Depth to Water (ft)	Water Level Elevation (feet)	Comments
3/23/2007		195.00	1,685	
4/25/2007	1:52 PM	199.62	1,681	
5/16/2007	4:32 PM	202.34	1,678	
6/26/2007	4:25 PM	204.59	1,676	
7/20/2007	9:30 AM	240.00	1,640	
8/15/2007	12:50 PM	249.16	1,631	
9/27/2007	-	255.91	1,624	
10/18/2007	2:00 PM	270.20	1,610	
11/29/2007	8:45 AM	244.79	1,635	

Park Sierra Dr.

Well head elevation 1,805.7 ft

Distance from M.Pt. to G.S 1.0 ft

Total Depth of Well 450 ft

Date of Measurement	Time	Depth to Water (ft)	Water Level Elevation (feet)	Comments
3/23/2007		193.00	1,677	
4/25/2007	1:45 PM	199.72	1,605	
5/16/2007	4:22 PM	201.65	1,603
